# RINGS OF INTEGERS WITHOUT A POWER BASIS 

KEITH CONRAD

Let $K$ be a number field, with degree $n$ and ring of integers $\mathcal{O}_{K}$. If $\mathcal{O}_{K}=\mathbf{Z}[\alpha]$ for some $\alpha \in \mathcal{O}_{K}$, then $\left\{1, \alpha, \ldots, \alpha^{n-1}\right\}$ is a $\mathbf{Z}$-basis of $\mathcal{O}_{K}$. We call such a basis a power basis.

When $K$ is a quadratic field or a cyclotomic field, $\mathcal{O}_{K}$ admits a power basis, and the use of these two fields as examples in algebraic number theory can lead to the impression that rings of integers always have a power basis. This is false. While it is always true that

$$
\mathcal{O}_{K}=\mathbf{Z} e_{1} \oplus \cdots \oplus \mathbf{Z} e_{n}
$$

for some $e_{1}, \ldots, e_{n}$, often we can not choose the $e_{i}$ 's to be powers of a single number. We will describe the first known cubic field $K$ where $\mathcal{O}_{K}$ has no power basis, then describe an infinite set of Galois cubic fields whose ring of integers has no power basis, and then describe an infinite set of quadratic extensions of imaginary quadratic fields without a relative integral power basis.

## 1. Dedekind's cubic field

The following example is due to Dedekind. He showed how he found it in 1871 [1, pp. 1490-1492] (pp. 13-14 in the English translation). In later work, such as [2, pp. 30-36], it was introduced without explanation.
Theorem 1.1. Let $K=\mathbf{Q}(\theta)$ where $\theta$ is a root of $T^{3}-T^{2}-2 T-8=0 .{ }^{1}$ Then $\theta^{\prime}=4 / \theta$ is in $\mathcal{O}_{K}, \mathcal{O}_{K}=\mathbf{Z}+\mathbf{Z} \theta+\mathbf{Z} \theta^{\prime}$, and $\mathcal{O}_{K} \neq \mathbf{Z}[\alpha]$ for all $\alpha$ in $\mathcal{O}_{K}$.
Proof. The field $K$ is cubic since the polynomial is irreducible over $\mathbf{Q}$. By algebra,

$$
\begin{aligned}
\theta^{3}-\theta^{2}-2 \theta-8=0 & \Longrightarrow \frac{8}{\theta^{3}}+\frac{2}{\theta^{2}}+\frac{1}{\theta}-1=0 \\
& \Longrightarrow\left(\frac{4}{\theta}\right)^{3}+\left(\frac{4}{\theta}\right)^{2}+2 \frac{4}{\theta}-8=0
\end{aligned}
$$

so $\theta^{\prime}$ is a root of $T^{3}+T^{2}+2 T-8$ and thus $\theta^{\prime} \in \mathcal{O}_{K}$. From the cubic relations of $\theta$ and $\theta^{\prime}$ over $\mathbf{Q}$, we have $\theta^{\prime}=4 / \theta=\left(\theta^{2}-\theta\right) / 2-1$ and $\theta=4 / \theta^{\prime}=\left(\theta^{\prime 2}+\theta^{\prime}\right) / 2+1$. Therefore

$$
\begin{equation*}
\theta^{2}=2+\theta+2 \theta^{\prime}, \quad \theta^{\prime 2}=-2+2 \theta-\theta^{\prime}, \tag{1.1}
\end{equation*}
$$

so $\mathbf{Z}+\mathbf{Z} \theta+\mathbf{Z} \theta^{\prime}$ is a subring of $\mathcal{O}_{K}$. Using (1.1) and the values $\operatorname{Tr}(\theta)=1$ and $\operatorname{Tr}\left(\theta^{\prime}\right)=-1$, where $\operatorname{Tr}=\operatorname{Tr}_{K / \mathbf{Q}}$,

$$
\operatorname{disc}\left(\mathbf{Z}+\mathbf{Z} \theta+\mathbf{Z} \theta^{\prime}\right)=\operatorname{det}\left(\begin{array}{ccc}
\operatorname{Tr}(1) & \operatorname{Tr}(\theta) & \operatorname{Tr}\left(\theta^{\prime}\right) \\
\operatorname{Tr}(\theta) & \operatorname{Tr}\left(\theta^{2}\right) & \operatorname{Tr}\left(\theta \theta^{\prime}\right) \\
\operatorname{Tr}\left(\theta^{\prime}\right) & \operatorname{Tr}\left(\theta \theta^{\prime}\right) & \operatorname{Tr}\left(\theta^{\prime 2}\right)
\end{array}\right)=\operatorname{det}\left(\begin{array}{ccc}
3 & 1 & -1 \\
1 & 5 & 12 \\
-1 & 12 & -3
\end{array}\right)=-503
$$

which is a negative prime, and hence squarefree, so $\mathcal{O}_{K}=\mathbf{Z}+\mathbf{Z} \theta+\mathbf{Z} \theta^{\prime}$.

[^0]To show $\mathcal{O}_{K} \neq \mathbf{Z}[\alpha]$ for all $\alpha$ in $\mathcal{O}_{K}$, write $\alpha=a+b \theta+c \theta^{\prime}$ for integers $a, b$, and $c$. We may assume $b$ or $c$ is not 0 (otherwise $\alpha \in \mathbf{Z}$ and the result is obvious). Then $K=\mathbf{Q}(\alpha)$, so $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]<\infty$ : when a finite free $\mathbf{Z}$-module contains another finite-free $\mathbf{Z}$-module of the same rank, the index is finite. We will show $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ is even, so $\mathcal{O}_{K} \neq \mathbf{Z}[\alpha]$. The index can be computing from the matrix $A$ expressing $1, \alpha, \alpha^{2}$ as $\mathbf{Z}$-linear combinations of $1, \theta, \theta^{\prime}$ :

$$
\left(\begin{array}{c}
1 \\
\alpha \\
\alpha^{2}
\end{array}\right)=A\left(\begin{array}{c}
1 \\
\theta \\
\theta^{\prime}
\end{array}\right) \Longrightarrow\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]=|\operatorname{det} A|
$$

by Theorem 5.19 in https://kconrad.math.uconn.edu/blurbs/linmultialg/modules overPID.pdf.

To compute det $A$, we may assume $a=0$ since $\mathbf{Z}[\alpha]=\mathbf{Z}[\alpha-a]$. Then

$$
\begin{aligned}
\alpha^{2} & =\left(b \theta+c \theta^{\prime}\right)^{2} \\
& =b^{2} \theta^{2}+2 b c\left(\theta \theta^{\prime}\right)+c^{2} \theta^{\prime 2} \\
& =b^{2}\left(2+\theta+2 \theta^{\prime}\right)+8 b c+c^{2}\left(-2+2 \theta-\theta^{\prime}\right) \quad \text { by }(1.1) \\
& =\left(2 b^{2}+8 b c-2 c^{2}\right)+\left(b^{2}+2 c^{2}\right) \theta+\left(2 b^{2}-c^{2}\right) \theta^{\prime},
\end{aligned}
$$

so

$$
\left(\begin{array}{c}
1 \\
\alpha \\
\alpha^{2}
\end{array}\right)=\left(\begin{array}{ccc}
1 & 0 & 0 \\
0 & b & c \\
2 b^{2}+8 b c-2 c^{2} & b^{2}+2 c^{2} & 2 b^{2}-c^{2}
\end{array}\right)\left(\begin{array}{c}
1 \\
\theta \\
\theta^{\prime}
\end{array}\right)
$$

and the determinant of the matrix modulo 2 is $-b c^{2}-c b^{2}=-b c(c+b)$, which is even for all integers $b$ and $c$. Thus $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ is even.

Corollary 1.2. As $\alpha$ runs over $\mathcal{O}_{K}-\mathbf{Z}$, the gcd of the integers $\operatorname{disc}(\mathbf{Z}[\alpha])$ is $4 \cdot 503$.
Proof. We have $\operatorname{disc}(\mathbf{Z}[\alpha])=\operatorname{disc}\left(\mathcal{O}_{K}\right)\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]^{2}$, where $\operatorname{disc}\left(\mathcal{O}_{K}\right)=-503$ and $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ is even, so $\operatorname{disc}(\mathbf{Z}[\alpha])$ is divisible by $4 \cdot 503$. The gcd of these numbers is $4 \cdot 503$ since $\operatorname{disc}(\mathbf{Z}[\theta])=-4 \cdot 503$ :

$$
\mathbf{Z}[\theta]=\mathbf{Z}+\mathbf{Z} \theta+\mathbf{Z} \theta^{2}=\mathbf{Z}+\mathbf{Z} \theta+\mathbf{Z} 2 \theta^{\prime}
$$

since $\theta^{2}=2+\theta+2 \theta^{\prime}$, so $\left[\mathcal{O}_{K}: \mathbf{Z}[\theta]\right]=2$.

## 2. Many cubic Galois extensions without a power basis

We now describe infinitely many Galois cubic extensions of $\mathbf{Q}$ whose ring of integers has no power basis.

Fix a prime $p \equiv 1 \bmod 3$. Since $\operatorname{Gal}\left(\mathbf{Q}\left(\zeta_{p}\right) / \mathbf{Q}\right) \cong(\mathbf{Z} / p \mathbf{Z})^{\times}$is cyclic, there is a unique cubic subfield $F_{p}$ in $\mathbf{Q}\left(\zeta_{p}\right)$ and $\operatorname{Gal}\left(F_{p} / \mathbf{Q}\right)$ is the quotient of $(\mathbf{Z} / p \mathbf{Z})^{\times}$by its subgroup of cubes. In particular, for each prime $q \neq p, q$ splits completely in $F_{p}$ if and only if the Frobenius of $q$ in $\operatorname{Gal}\left(F_{p} / \mathbf{Q}\right)$ is trivial, which is equivalent to $q$ being a cube modulo $p$.

Theorem 2.1. If $p \equiv 1 \bmod 3$ and 2 is a cube in $\mathbf{Z} / p \mathbf{Z}$, then $\mathcal{O}_{F_{p}} \neq \mathbf{Z}[\alpha]$ for all $\alpha \in \mathcal{O}_{F_{p}}$ such that $F=\mathbf{Q}(\alpha)$.

Proof. Suppose $\mathcal{O}_{F_{p}}=\mathbf{Z}[\alpha]$ for some $\alpha$. Let $\alpha$ have minimal polynomial $f(T)$ over $\mathbf{Q}$, so $f$ is an irreducible cubic in $\mathbf{Z}[T]$. Then

$$
\mathcal{O}_{F_{p}}=\mathbf{Z}[\alpha] \cong \mathbf{Z}[T] / f(T)
$$

Since $2 \bmod p$ is a cube, 2 splits completely in $F_{p}$, so $f(T)$ splits completely in $(\mathbf{Z} / 2 \mathbf{Z})[T]$ : $f(T)$ is a product of three distinct monic linear polynomials. But $(\mathbf{Z} / 2 \mathbf{Z})[T]$ only has two such polynomials, $T$ and $T+1$. We have a contradiction, so $\mathcal{O}_{F_{p}} \neq \mathbf{Z}[\alpha]$ for all $\alpha$.

The primes that fit the hypotheses of Theorem 2.1 are those $p \equiv 1 \bmod 3$ such that $2^{(p-1) / 3} \equiv 1 \bmod p$. These are the primes that split completely in the splitting field of $T^{3}-2$ over $\mathbf{Q}$, and by the Chebotarev density theorem there are infinitely many such $p$ and their proportion among all primes is $1 / 6$. The first few are $31,43,109$, and 127. For each such $p$, Theorem 2.1 tells us the ring of integers of $F_{p}$ does not have a power basis.

Remark 2.2. That the ring of integers of Dedekind's cubic field $\mathbf{Q}(\theta)$ lacks a power basis can be proved using the same principle as Theorem 2.1: show 2 splits completely in the field, and that implies its ring of integers has no power basis for the same reason as in Theorem 2.1. However, to show directly that 2 splits completely in $\mathbf{Q}(\theta)$ requires techniques other than those we used in the fields $F_{p}$, since Dedekind's cubic field is not in a cyclotomic field (for example, $\mathbf{Q}(\theta)$ is not Galois over $\mathbf{Q}$ ).

For a cubic field $K$, it can be shown that 2 splits completely in $K$ if and only if $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ is even for all $\alpha \in \mathcal{O}_{K}-\mathbf{Z}$. Having the index always be even implies $\mathcal{O}_{K} \neq \mathbf{Z}[\alpha]$ for all $\alpha$ since the index can't be 1. In 1882, Kronecker [7, p. 119] said he found an example in 1858 of a field $K$ in $\mathbf{Q}\left(\zeta_{13}\right)$ where $\mathcal{O}_{K}$ has no power basis over $\mathbf{Z}$. It is the quartic subfield $K$, and it turns out that $3 \mid\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ for all $\alpha \in \mathcal{O}_{K}$ such that $K=\mathbf{Q}(\alpha)$.

A broader context for $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ always being even is a prime $p$ satisfying $p \mid\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ for all $\alpha \in \mathcal{O}_{K}$ such that $K=\mathbf{Q}(\alpha)$. Call such $p$ a common index divisor for $K$. The existence of such $p$ is sufficient for $\mathcal{O}_{K}$ not to have a power basis. ${ }^{2}$ Dedekind [2, Sect. 4] (and later Hensel [5, p. 138]) showed a prime $p$ is a common index divisor for a number field $K$ if and only if there is $d \geq 1$ such that the number of different prime ideal factors of $p \mathcal{O}_{K}$ with residue field degree $d$ is greater than the number of monic irreducibles of degree $d$ in $\mathbf{F}_{p}[T] .^{3}$ In particular, if $[K: \mathbf{Q}] \geq 3$ and 2 splits completely, then $\left[\mathcal{O}_{K}: \mathbf{Z}[\alpha]\right]$ is even for all $\alpha \in \mathcal{O}_{K}$ such that $K=\mathbf{Q}(\alpha)$, since there are only two monic irreducibles of degree 1 in $\mathbf{F}_{2}[T]$. (A prime $p$ that is a common index divisor for a number field $K$ must be less than $[K: \mathbf{Q}]$ by a theorem of von Zylinski [10]. ${ }^{4}$ ) See [3] for a proof that there are infinitely many cubic fields without a power basis for which this even-index condition does not apply.

When $p \equiv 1 \bmod 3, \mathcal{O}_{F_{p}}$ has no power basis. What is a $\mathbf{Z}$-basis for it?
Theorem 2.3. For $p \equiv 1 \bmod 3$, let $r \in(\mathbf{Z} / p \mathbf{Z})^{\times}$have order 3. Then $\mathcal{O}_{F_{p}}=\mathbf{Z} \eta_{0}+\mathbf{Z} \eta_{1}+$ $\mathbf{Z} \eta_{2}$, where

$$
\eta_{0}=\operatorname{Tr}_{\mathbf{Q}\left(\zeta_{p}\right) / F_{p}}\left(\zeta_{p}\right)=\sum_{t^{(p-1) / 3 \equiv 1 \bmod p}} \zeta_{p}^{t}, \quad \eta_{1}=\sum_{t^{(p-1) / 3 \equiv r \bmod p}} \zeta_{p}^{t}, \quad \eta_{2}=\sum_{t^{(p-1) / 3 \equiv r^{2} \bmod p}} \zeta_{p}^{t} .
$$

The numbers $\eta_{i}$ are examples of (cyclotomic) periods [9, pp. 16-17].

[^1]Proof. For $c \in(\mathbf{Z} / p \mathbf{Z})^{\times}, c^{(p-1) / 3}$ is a cube root of unity and therefore is in $\left\{1, r, r^{2}\right\}$. For suitable $c$ each of the three values is achieved. Let $\sigma_{c} \in \operatorname{Gal}\left(\mathbf{Q}\left(\zeta_{p}\right) / \mathbf{Q}\right)$ send $\zeta_{p}$ to $\zeta_{p}^{c}$. Then

$$
\sigma_{c}\left(\eta_{i}\right)=\sigma_{c}\left(\sum_{t^{(p-1) / 3} \equiv r^{i} \bmod p} \zeta_{p}^{t}\right)=\sum_{t^{(p-1) / 3} \equiv r^{i} \bmod p} \zeta_{p}^{c t}=\sum_{t^{(p-1) / 3} \equiv c^{(p-1) / 3 r^{i} \bmod p}} \zeta_{p}^{t},
$$

so $\sigma_{c}$ permutes $\left\{\eta_{0}, \eta_{1}, \eta_{2}\right\}$ the same way multiplication by $c^{(p-1) / 3}$ permutes $\left\{1, r, r^{2}\right\}$. Therefore $\eta_{0}, \eta_{1}$, and $\eta_{2}$ are $\mathbf{Q}$-conjugates, and since $F_{p}$ is the unique cubic subfield of $\mathbf{Q}\left(\zeta_{p}\right)$ each of $\eta_{0}, \eta_{1}, \eta_{2}$ generates $F_{p}$ as a field extension of $\mathbf{Q}$.

The standard basis of $\mathbf{Q}\left(\zeta_{p}\right)$ over $\mathbf{Q}$ is $\left\{1, \zeta_{p}, \ldots, \zeta_{p}^{p-2}\right\}$, and this is also a basis for $\mathbf{Z}\left[\zeta_{p}\right]$ over $\mathbf{Z}$. It is more convenient to multiply through by $\zeta_{p}$ and use instead $\mathcal{B}=$ $\left\{\zeta_{p}, \zeta_{p}, \ldots, \zeta_{p}^{p-1}\right\}$ as a basis of $\mathbf{Q}\left(\zeta_{p}\right)$ over $\mathbf{Q}$ or $\mathbf{Z}\left[\zeta_{p}\right]$ over $\mathbf{Z}$, since this is a basis of Galois conjugates (a normal basis over $\mathbf{Q}$ ). For example, $\eta_{0}, \eta_{1}, \eta_{2}$ are sums of different numbers in $\mathcal{B}$, so $\eta_{0}, \eta_{1}$, and $\eta_{2}$ are linearly independent over $\mathbf{Q}$ and thus form a $\mathbf{Q}$-basis of $F_{p}$.

Each $x \in \mathcal{O}_{F_{p}}$ has the form $x=a_{0} \eta_{0}+a_{1} \eta_{1}+a_{2} \eta_{2}$ for $a_{0}, a_{1}, a_{2} \in \mathbf{Q}$. On the left side, since $x$ is an algebraic integer in $\mathbf{Q}\left(\zeta_{p}\right)$ it is a $\mathbf{Z}$-linear combination of the numbers in $\mathcal{B}$. Expanding the right side in terms of $\mathcal{B}$, the coefficients are $a_{0}, a_{1}$, and $a_{2}$, so comparing coefficients of the numbers in $\mathcal{B}$ on both sides shows $a_{0}, a_{1}$, and $a_{2}$ are all integers.

To measure how far $\mathbf{Z}\left[\eta_{0}\right]$ is from the full ring of integers $\mathcal{O}_{F_{p}}$ we'd like to compute the index $\left[\mathcal{O}_{F_{p}}: \mathbf{Z}\left[\eta_{0}\right]\right]$. This can be expressed in terms of discriminants: if $f(T) \in \mathbf{Z}[T]$ is the minimal polynomial of $\eta_{0}$ over $\mathbf{Q}$ then

$$
\begin{equation*}
\operatorname{disc}(f(T))=\left[\mathcal{O}_{F_{p}}: \mathbf{Z}\left[\eta_{0}\right]\right]^{2} \operatorname{disc}\left(\mathcal{O}_{F_{p}}\right) . \tag{2.1}
\end{equation*}
$$

What are these discriminants?
Theorem 2.4. For $p \equiv 1 \bmod 3, \operatorname{disc}\left(\mathcal{O}_{F_{p}}\right)=p^{2}$.
Proof. The discriminant of $\mathcal{O}_{F_{p}}$ is the $3 \times 3$ determinant

$$
\left|\begin{array}{ccc}
\operatorname{Tr}\left(\eta_{0}^{2}\right) & \operatorname{Tr}\left(\eta_{0} \eta_{1}\right) & \operatorname{Tr}\left(\eta_{0} \eta_{2}\right) \\
\operatorname{Tr}\left(\eta_{1} \eta_{0}\right) & \operatorname{Tr}\left(\eta_{1}^{2}\right) & \operatorname{Tr}\left(\eta_{1} \eta_{2}\right) \\
\operatorname{Tr}\left(\eta_{2} \eta_{0}\right) & \operatorname{Tr}\left(\eta_{2} \eta_{1}\right) & \operatorname{Tr}\left(\eta_{2}^{2}\right)
\end{array}\right|,
$$

where $\operatorname{Tr}=\operatorname{Tr}_{F_{p} / \mathbf{Q}}$. Since $\eta_{0}, \eta_{1}, \eta_{2}$ are $\mathbf{Q}$-conjugates, as are $\eta_{0} \eta_{1}, \eta_{0} \eta_{2}$, and $\eta_{1} \eta_{2}$, we have

$$
\begin{align*}
\operatorname{disc}\left(\mathcal{O}_{F_{p}}\right) & =\left|\begin{array}{ccc}
\operatorname{Tr}\left(\eta_{0}^{2}\right) & \operatorname{Tr}\left(\eta_{0} \eta_{1}\right) & \operatorname{Tr}\left(\eta_{0} \eta_{1}\right) \\
\operatorname{Tr}\left(\eta_{0} \eta_{1}\right) & \operatorname{Tr}\left(\eta_{0}^{2}\right) & \operatorname{Tr}\left(\eta_{0} \eta_{1}\right) \\
\operatorname{Tr}\left(\eta_{0} \eta_{1}\right) & \operatorname{Tr}\left(\eta_{0} \eta_{1}\right) & \operatorname{Tr}\left(\eta_{0}^{2}\right)
\end{array}\right| \\
& =a^{3}-3 a b^{2}+2 b^{3}, \tag{2.2}
\end{align*}
$$

where $a=\operatorname{Tr}\left(\eta_{0}^{2}\right)$ and $b=\operatorname{Tr}\left(\eta_{0} \eta_{1}\right)$.

The trace of $\eta_{0}$ is $\operatorname{Tr}\left(\eta_{0}\right)=\eta_{0}+\eta_{1}+\eta_{2}=\sum_{(t, p)=1} \zeta_{p}^{t}=-1$. To compute $\operatorname{Tr}\left(\eta_{0}^{2}\right)$, we compute

$$
\begin{align*}
\eta_{0}^{2} & =\sum_{a^{(p-1) / 3}=1} \sum_{b^{(p-1) / 3}=1} \zeta_{p}^{a+b} \\
& =\sum_{a^{(p-1) / 3}=1} \sum_{b^{(p-1) / 3}=1} \zeta_{p}^{a(1+b)} \\
& =\sum_{b^{(p-1) / 3}=1} \sum_{a^{(p-1) / 3}=1} \zeta_{p}^{a(1+b)} \\
& =\frac{p-1}{3}+\sum_{b^{(p-1) / 3}=1, b \neq-1} \sigma_{1+b}\left(\eta_{0}\right) \\
& =\frac{p-1}{3}+c_{0} \eta_{0}+c_{1} \eta_{1}+c_{2} \eta_{2}, \tag{2.3}
\end{align*}
$$

where

$$
\begin{aligned}
& c_{0}=\left|\left\{b \neq 0,-1: b^{(p-1) / 3}=1,(1+b)^{(p-1) / 3}=1\right\}\right|, \\
& c_{1}=\left|\left\{b \neq 0,-1: b^{(p-1) / 3}=1,(1+b)^{(p-1) / 3}=r\right\}\right|, \\
& c_{2}=\left|\left\{b \neq 0,-1: b^{(p-1) / 3}=1,(1+b)^{(p-1) / 3}=r^{2}\right\}\right| .
\end{aligned}
$$

(Recall $r$ and $r^{2}$ are the elements of order 3 in $(\mathbf{Z} / p \mathbf{Z})^{\times}$.)
Taking the trace of both sides of (2.3) gives

$$
\operatorname{Tr}\left(\eta_{0}^{2}\right)=(p-1)+\left(c_{0}+c_{1}+c_{2}\right) \operatorname{Tr}\left(\eta_{0}\right)=p-1-\left(c_{0}+c_{1}+c_{2}\right) .
$$

The sum of the $c_{i}$ 's is the number of solutions to $b^{(p-1) / 3}=1$ in $\mathbf{Z} / p \mathbf{Z}$ except for $b=-1$, so

$$
\begin{equation*}
\operatorname{Tr}\left(\eta_{0}^{2}\right)=p-1-\left(\frac{p-1}{3}-1\right)=\frac{2}{3}(p-1)+1 \tag{2.4}
\end{equation*}
$$

Writing

$$
\begin{align*}
\operatorname{Tr}\left(\eta_{0}^{2}\right) & =\eta_{0}^{2}+\eta_{1}^{2}+\eta_{2}^{2} \\
& =\left(\eta_{0}+\eta_{1}+\eta_{2}\right)^{2}-2\left(\eta_{0} \eta_{1}+\eta_{1} \eta_{2}+\eta_{0} \eta_{2}\right) \\
& =\left(\operatorname{Tr} \eta_{0}\right)^{2}-2 \operatorname{Tr}\left(\eta_{0} \eta_{1}\right) \\
& =1-2 \operatorname{Tr}\left(\eta_{0} \eta_{1}\right), \tag{2.5}
\end{align*}
$$

we compare (2.4) and (2.5) to see that $\operatorname{Tr}\left(\eta_{0} \eta_{1}\right)=-(p-1) / 3$.
Feeding the formulas for $\operatorname{Tr}\left(\eta_{0}^{2}\right)$ and $\operatorname{Tr}\left(\eta_{0} \eta_{1}\right)$ into the discriminant formula (2.2) gives

$$
\operatorname{disc}\left(\mathcal{O}_{F_{p}}\right)=\left(\frac{2}{3}(p-1)+1\right)^{3}-3\left(\frac{2}{3}(p-1)+1\right)\left(\frac{p-1}{3}\right)^{2}-2\left(\frac{p-1}{3}\right)^{3}=p^{2} .
$$

Remark 2.5. The discriminant of $F_{p}$ can be calculated using ramification rather than a basis: the extension $\mathbf{Q}\left(\zeta_{p}\right) / \mathbf{Q}$ is ramified only at $p$, so if $K$ is an intermediate field then it is ramified only at $p$ too. Since $\mathbf{Q}\left(\zeta_{p}\right) / \mathbf{Q}$ is totally ramified at $p, K$ is totally ramified at $p$ as well. If a number field is totally ramified at a prime $p$ and has degree $n$ not divisible by $p$ then it can be shown that its discriminant is divisible by $p^{n-1}$ but not $p^{n}$. Therefore if $[K: \mathbf{Q}]=d, \operatorname{disc}(K)= \pm p^{d-1}$. The sign of $\operatorname{disc}(K)$ is $(-1)^{r_{2}(K)}$ [9, Lemma 2.2], and when $p \equiv 1 \bmod 3$ the cubic field $F_{p}$ has $r_{2}=0$ since a Galois cubic with a real embedding has $r_{2}=0$, so $\operatorname{disc}\left(F_{p}\right)=p^{3-1}=p^{2}$.

The first few primes $p \equiv 1 \bmod 3$ are

$$
7,13,19,31,37,43,61,67,73,79,97 .
$$

For every prime $p \equiv 1 \bmod 3$ we can write $4 p=A^{2}+27 B^{2}$ and such an equation determines $A$ and $B$ up to sign [6, p. 119]. The table below gives the positive $A$ and $B$ for the above $p$.

| $p$ | 7 | 13 | 19 | 31 | 37 | 43 | 61 | 67 | 73 | 79 | 97 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $(A, B)$ | $(1,1)$ | $(5,1)$ | $(7,1)$ | $(4,2)$ | $(11,1)$ | $(8,2)$ | $(1,3)$ | $(5,3)$ | $(7,3)$ | $(17,1)$ | $(19,1)$ |

Numerically, for each of the above $p$ a calculation of $f(T)$ as $\left(T-\eta_{0}\right)\left(T-\eta_{1}\right)\left(T-\eta_{2}\right)$ shows the discriminant of $f(T)$ is $(p B)^{2}$. By (2.1) and Theorem 2.4, the formula $\operatorname{disc}(f(T))=$ $(p B)^{2}$ is equivalent to $\left[\mathcal{O}_{F_{p}}: \mathbf{Z}\left[\eta_{0}\right]\right]=|B|$, so by the above table $\mathbf{Z}\left[\eta_{0}\right]$ has index 2 in $\mathcal{O}_{F_{p}}$ when $p$ is 31 and 43, the index is 3 when $p$ is 61,67 , and 73 , and the index is 1 (i.e., $\left.\mathcal{O}_{F_{p}}=\mathbf{Z}\left[\eta_{0}\right]\right)$ for the other $p$ in the table. For a more rigorous discussion of the formula $\operatorname{disc}(f(T))=(p B)^{2}$, see [4]. Claude Quitte observed numerically for the above $p$ an index formula using $A:\left[\mathcal{O}_{F_{p}}: \mathbf{Z}\left[\eta_{0}-\eta_{1}\right]\right]=|A|$.

The formula $\operatorname{disc}(f(T))=(p B)^{2}$ leads to a formula for $f(T)$. In terms of its roots $\eta_{i}$,

$$
\begin{aligned}
f(T) & =\left(T-\eta_{0}\right)\left(T-\eta_{1}\right)\left(T-\eta_{2}\right) \\
& =T^{3}-\left(\eta_{0}+\eta_{1}+\eta_{2}\right) T^{2}+\left(\eta_{0} \eta_{1}+\eta_{0} \eta_{2}+\eta_{1} \eta_{2}\right) T-\eta_{0} \eta_{1} \eta_{2} \\
& =T^{3}-\operatorname{Tr}\left(\eta_{0}\right) T^{2}+\operatorname{Tr}\left(\eta_{0} \eta_{1}\right) T-\eta_{0} \eta_{1} \eta_{2} \\
& =T^{3}-(-1) T^{2}-\frac{p-1}{3} T-\eta_{0} \eta_{1} \eta_{2} \\
& =T^{3}+T^{2}-\frac{p-1}{3} T-\eta_{0} \eta_{1} \eta_{2} .
\end{aligned}
$$

We want to write the constant term of $f(T)$ in terms of $p$. The general formula

$$
\operatorname{disc}\left(T^{3}+T^{2}+a T+b\right)=-4 a^{3}+a^{2}+18 a b-27 b^{2}-4 b
$$

with $a=-(p-1) / 3$ and $b=-\eta_{0} \eta_{1} \eta_{2}$ is

$$
\begin{aligned}
\frac{4}{27} p^{3}-\frac{1}{3} p^{2}+\left(\frac{2}{9}-6 b\right) p-27 b^{2}+2 b-\frac{1}{27} & =\frac{p^{2}}{27}\left(4 p-9-\frac{6(27 b-1)}{p}-\frac{(27 b-1)^{2}}{p^{2}}\right) \\
& =\frac{p^{2}}{27}\left(4 p-\left(3+\frac{27 b-1}{p}\right)^{2}\right)
\end{aligned}
$$

Setting $4 p=A^{2}+27 B^{2}$, this discriminant is

$$
\frac{p^{2}}{27}\left(A^{2}+27 B^{2}-\left(3+\frac{27 b-1}{p}\right)^{2}\right)=\frac{p^{2}}{27}\left(A^{2}-\left(3+\frac{27 b-1}{p}\right)^{2}\right)+(p B)^{2}
$$

Therefore

$$
\operatorname{disc}(f(T))=(p B)^{2} \Longleftrightarrow 3+\frac{27 b-1}{p}= \pm A
$$

Since $p \equiv 1 \bmod 3$ we have $3+(27 b-1) / p \equiv-1 \bmod 3$, so if we choose the sign on $A$ to make $A \equiv 1 \bmod 3$ then $3+(27 b-1) / p=-A$. Rewrite this as $b=(1-p(A+3)) / 27$, so the minimal polynomial of $\eta_{0}$ over $\mathbf{Q}$ is

$$
\begin{equation*}
f(T)=T^{3}+T^{2}-\frac{p-1}{3} T+\frac{1-p(A+3)}{27} \tag{2.6}
\end{equation*}
$$

with $4 p=A^{2}+27 B^{2}$ and $A \equiv 1 \bmod 3$.

Example 2.6. The first $p$ fitting the hypotheses of Theorem 2.1 is $p=31$, for which $4 p=124=(4)^{2}+27(2)^{2}$. Therefore the cubic subfield of $\mathbf{Q}\left(\zeta_{31}\right)$ is $\mathbf{Q}\left(\eta_{0}\right)$ where, by (2.6), $\eta_{0}$ has minimal polynomial

$$
T^{3}+T^{2}-\frac{31-1}{3} T+\frac{1-31(4+3)}{27}=T^{3}+T^{2}-10 T-8 .
$$

The field $\mathbf{Q}\left(\eta_{0}\right)$ is a cyclic cubic extension of $\mathbf{Q}$ in which 2 splits completely and its ring of integers has no power basis.

Example 2.7. The second $p$ fitting the hypotheses of Theorem 2.1 is $p=43$, for which $4 p=172=(-8)^{2}+27(2)^{2}$ (we use -8 so that $A=-8 \equiv 1 \bmod 3$ ). Thus the cubic subfield of $\mathbf{Q}\left(\zeta_{43}\right)$ is $\mathbf{Q}\left(\eta_{0}\right)$ where $\eta_{0}$ has minimal polynomial

$$
T^{3}+T^{2}-\frac{43-1}{3} T+\frac{1-43(-8+3)}{27}=T^{3}+T^{2}-14 T+8
$$

and this cubic field has the same properties as at the end of the previous example.
The minimal polynomial of $\eta_{0}-\eta_{1}$ over $\mathbf{Q}$ is $\left(T-\left(\eta_{0}-\eta_{1}\right)\right)\left(T-\left(\eta_{1}-\eta_{2}\right)\right)\left(T-\left(\eta_{2}-\eta_{0}\right)\right)$. Expanding this out, we get

$$
\begin{equation*}
T^{3}+\left(\eta_{0} \eta_{1}+\eta_{0} \eta_{2}+\eta_{1} \eta_{2}-\eta_{0}^{2}-\eta_{1}^{2}-\eta_{2}^{2}\right) T+\left(\eta_{0}-\eta_{1}\right)\left(\eta_{1}-\eta_{2}\right)\left(\eta_{2}-\eta_{0}\right) \tag{2.7}
\end{equation*}
$$

The coefficient of $T$ is $3 \operatorname{Tr}\left(\eta_{0} \eta_{1}\right)-\left(\operatorname{Tr} \eta_{0}\right)^{2}=-3(p-1) / 3-(-1)^{2}=-p$ and the constant term is $\sqrt{\operatorname{disc}(f(T))}= \pm p|B|$. The sign of the constant term in (2.7) is sensitive to the choice of $\zeta_{p}$ and nontrivial cube root of unity $r \bmod p$ in the definition of the $\eta_{i}$, e.g., changing $r$ can change $\eta_{1}$ into $\eta_{2}$ but $\eta_{0}-\eta_{1}$ and $\eta_{0}-\eta_{2}$ are not $\mathbf{Q}$-conjugates. In fact $\eta_{0}-\eta_{2}$ has minimal polynomial $T^{3}-p T \mp p|B|$ with constant term of opposite sign to the minimal polynomial of $\eta_{0}-\eta_{1}$. When the definition of the $\eta_{i}$ uses $\zeta_{p}=e^{2 \pi i / p}$ and $r$ is the numerically least nontrivial cube root of unity $\bmod p$ in $\{1, \ldots, p-1\}$ then for all $p<100$ such that $p \equiv 1 \bmod 3$ the constant term of (2.7) turns out to be $p|B|$ except when $p=61$.

The only $p<500$ for which $p \equiv 1 \bmod 3$ and the class number of $F_{p}$ is greater than 1 are 163, 277, 313, 349, and 397. For these $p$ the class group of $F_{p}$ is $\mathbf{Z} / 2 \mathbf{Z} \times \mathbf{Z} / 2 \mathbf{Z}$ except for $p=313$, when it is $\mathbf{Z} / 7 \mathbf{Z}$.

## 3. Power bases in relative quadratic extensions

For number fields $E$ and $F$ where $F \subset E$, a power basis of $\mathcal{O}_{E}$ over $\mathcal{O}_{F}$ is called a relative integral power basis. If $\mathcal{O}_{F}$ is a PID, then $\mathcal{O}_{E}$ is a free $\mathcal{O}_{F}$-module, so $\mathcal{O}_{E}$ has an $\mathcal{O}_{F}$-basis, but there might not be a power basis over $\mathcal{O}_{F}$. We'll meet some examples of this when $E / F$ is a quadratic extension, and necessarily $F \neq \mathbf{Q}$ since the ring of integers of a quadratic field is always of the form $\mathbf{Z}[w]$ for some $w$.

Here is a property of a quadratic extension $E / F$ when $\mathcal{O}_{E}$ has a power basis over $\mathcal{O}_{F}$.
Theorem 3.1. If $[E: F]=2$ and $\mathcal{O}_{E}=\mathcal{O}_{F}[\alpha]$ for some $\alpha$, then $\mathcal{O}_{E} / \mathcal{O}_{F} \cong \mathcal{O}_{F}$ as $\mathcal{O}_{F^{-}}$ modules.

Proof. If $\mathcal{O}_{E}=\mathcal{O}_{F}+\mathcal{O}_{F} \alpha$ for some nonzero $\alpha$ in $\mathcal{O}_{E}$, then $\mathcal{O}_{E}=\mathcal{O}_{F} \oplus \mathcal{O}_{F} \alpha$, so $\mathcal{O}_{E} / \mathcal{O}_{F} \cong$ $\mathcal{O}_{F} \alpha \cong \mathcal{O}_{F}$ as $\mathcal{O}_{F}$-modules.

Here are quadratic extensions of imaginary quadratic fields with no relative integral power basis. It is based on an answer to https://math.stackexchange.com/questions/4620044.

Example 3.2. Let $d$ be an even squarefree integer and $q$ be a prime not dividing $d$ such that $q \equiv 1 \bmod 4$. Set $F=\mathbf{Q}(\sqrt{-q})$ and $E=F(\sqrt{d})=\mathbf{Q}(\sqrt{-q}, \sqrt{d})$. It can be shown that $\mathcal{O}_{E}=\mathcal{O}_{F} \oplus \mathfrak{p} \sqrt{d} / 2$ where $\mathfrak{p}=(2,1+\sqrt{-q})$ is a nonprincipal ideal. ${ }^{5}$ Then $\mathcal{O}_{E} / \mathcal{O}_{F} \cong \mathfrak{p}$ as $\mathcal{O}_{F}$-modules and $\mathfrak{p} \neq \mathcal{O}_{F}$ since an ideal in $\mathcal{O}_{F}$ that is isomorphic to $\mathcal{O}_{F}$ as an $\mathcal{O}_{F}$-module must be a principal ideal. ${ }^{6}$ So $\mathcal{O}_{E}$ is not of the form $\mathcal{O}_{F}[\alpha]$ by Theorem 3.1.

In that example, $\mathcal{O}_{F}$ is not a PID (it has the nonprincipal ideal $\mathfrak{p}$ ). The next theorem shows that it was necessary for $\mathcal{O}_{F}$ not to be a PID.

Theorem 3.3. If $[E: F]=2$ and $\mathcal{O}_{F}$ is a PID, then $\mathcal{O}_{E}=\mathcal{O}_{F}[\alpha]$ for some $\alpha$.
Proof. Since $\mathcal{O}_{F}$ is a PID, $\mathcal{O}_{E}$ has an $\mathcal{O}_{F}$-basis $\left\{e_{1}, e_{2}\right\}$. In terms of this basis, we can write

$$
1=a_{1} e_{1}+a_{2} e_{2}
$$

for some $a_{1}$ and $a_{2}$ in $\mathcal{O}_{F}$. That equation implies a common factor of $a_{1}$ and $a_{2}$ in $\mathcal{O}_{F}$ is a unit in $\mathcal{O}_{E}$, and thus is a unit in $\mathcal{O}_{F}$, so $a_{1}$ and $a_{2}$ are relatively prime in $\mathcal{O}_{F}$. Since $\mathcal{O}_{F}$ is a PID,

$$
a_{1} b_{1}+a_{2} b_{2}=1
$$

for some $b_{1}$ and $b_{2}$ in $\mathcal{O}_{F}$. Then

$$
\left(\begin{array}{cc}
a_{1} & a_{2} \\
-b_{2} & b_{1}
\end{array}\right)\binom{e_{1}}{e_{2}}=\binom{1}{\alpha}
$$

for some $\alpha \in \mathcal{O}_{F}$ and that $2 \times 2$ matrix has determinant 1 , so 1 and $\alpha$ have the same $\mathcal{O}_{F}$-span as $e_{1}$ and $e_{2}$. Hence

$$
\mathcal{O}_{E}=\mathcal{O}_{F}+\mathcal{O}_{F} \alpha=\mathcal{O}_{F}[\alpha] .
$$
