# OSTROWSKI FOR NUMBER FIELDS 

KEITH CONRAD

## 1. Introduction

In 1916, Ostrowski [6] classified the nontrivial absolute values on Q: up to equivalence, they are the usual (archimedean) absolute value and the $p$-adic absolute values for different primes $p$, with none of these being equivalent to each other. We will see how this theorem extends to a number field $K$, giving a list of all the nontrivial absolute values on $K$ up to equivalence: for each nonzero prime ideal $\mathfrak{p}$ in $\mathcal{O}_{K}$ there is a $\mathfrak{p}$-adic absolute value, real embeddings of $K$ and complex embeddings of $K$ up to conjugation lead to archimedean absolute values on $K$, and every nontrivial absolute value on $K$ is equivalent to a $\mathfrak{p}$-adic, real, or complex absolute value.

## 2. Defining nontrivial absolute values on $K$

For each nonzero prime ideal $\mathfrak{p}$ in $\mathcal{O}_{K}$, a $\mathfrak{p}$-adic absolute value on $K$ is defined in terms of a $\mathfrak{p}$-adic valuation $\operatorname{ord}_{\mathfrak{p}}$ that is first defined on $\mathcal{O}_{K}-\{0\}$ and extended to $K^{\times}$by taking ratios.

Definition 2.1. For $x \in \mathcal{O}_{K}-\{0\}$, define $\operatorname{ord}_{\mathfrak{p}}(x):=m$ where $x \mathcal{O}_{K}=\mathfrak{p}^{m} \mathfrak{a}$ with $m \geq 0$ and $\mathfrak{p} \nmid \mathfrak{a}$.

We have $\operatorname{ord}_{\mathfrak{p}}(x y)=\operatorname{ord}_{\mathfrak{p}}(x)+\operatorname{ord}_{\mathfrak{p}}(y)$ for nonzero $x$ and $y$ in $\mathcal{O}_{K}$ by unique factorization of ideals in $\mathcal{O}_{K}$. This lets us extend $\operatorname{ord}_{\mathfrak{p}}$ to $K^{\times}$by using ratios of nonzero numbers in $\mathcal{O}_{K}$ : for $\alpha \in K^{\times}$, write $\alpha=x / y$ for nonzero $x$ and $y$ in $\mathcal{O}_{K}$ and set $\operatorname{ord}_{\mathfrak{p}}(\alpha):=\operatorname{ord}_{\mathfrak{p}}(x)-\operatorname{ord}_{\mathfrak{p}}(y)$. To see this is well-defined, if $x / y=x^{\prime} / y^{\prime}$ for nonzero $x, y, x^{\prime}$, and $y^{\prime}$ in $\mathcal{O}_{K}$ then $x y^{\prime}=x^{\prime} y$ in $\mathcal{O}_{K}$, which implies $\operatorname{ord}_{\mathfrak{p}}(x)+\operatorname{ord}_{\mathfrak{p}}\left(y^{\prime}\right)=\operatorname{ord}_{\mathfrak{p}}\left(x^{\prime}\right)+\operatorname{ord}_{\mathfrak{p}}(y)$, so $\operatorname{ord}_{\mathfrak{p}}(x)-\operatorname{ord}_{\mathfrak{p}}(y)=$ $\operatorname{ord}_{\mathfrak{p}}\left(x^{\prime}\right)-\operatorname{ord}_{\mathfrak{p}}\left(y^{\prime}\right)$. On $K^{\times}$we have $\operatorname{ord}_{\mathfrak{p}}(\alpha \beta)=\operatorname{ord}_{\mathfrak{p}}(\alpha)+\operatorname{ord}_{\mathfrak{p}}(\beta)$ for $\alpha, \beta \in K^{\times}$, so $\operatorname{ord}_{\mathfrak{p}}: K^{\times} \rightarrow \mathbf{Z}$ is a homomorphism that is surjective (for $x \in \mathfrak{p}-\mathfrak{p}^{2}$ we have $\operatorname{ord}_{\mathfrak{p}}(x)=1$ ). We set $\operatorname{ord}_{\mathfrak{p}}(0)=\infty$, where $\infty>n$ for each integer $n$.

On $\mathcal{O}_{K}, \operatorname{ord}_{\mathfrak{p}}(x+y) \geq \min \left(\operatorname{ord}_{\mathfrak{p}}(x), \operatorname{ord}_{\mathfrak{p}}(y)\right)$. First, if $x, y$, or $x+y$ is 0 then the inequality is simple to check. Next, if $x, y$, and $x+y$ are all nonzero and $m:=\min \left(\operatorname{ord}_{\mathfrak{p}}(x), \operatorname{ord}_{\mathfrak{p}}(y)\right)$ then $\mathfrak{p}^{m} \mid x \mathcal{O}_{K}$ and $\mathfrak{p}^{m} \mid y \mathcal{O}_{K}$, so $x$ and $y$ are in $\mathfrak{p}^{m}$. Then $x+y \in \mathfrak{p}^{m}$, so $\operatorname{ord}_{\mathfrak{p}}(x+y) \geq$ $m$. This inequality extends from $\mathcal{O}_{K}$ to $K$ by using a common denominator in ratios: $\operatorname{ord}_{\mathfrak{p}}(\alpha+\beta) \geq \min \left(\operatorname{ord}_{\mathfrak{p}}(\alpha), \operatorname{ord}_{\mathfrak{p}}(\beta)\right)$ for all $\alpha$ and $\beta$ in $K$. Therefore $\operatorname{ord}_{\mathfrak{p}}$ is a valuation on $K$.

Definition 2.2. Fixing a constant $c \in(0,1)$, set $|\alpha|=c^{\operatorname{ord}_{p}(\alpha)}$ for $\alpha \in K^{\times}$, and $|0|=0$. This is called a $\mathfrak{p}$-adic absolute value on $K$.

That the function $\alpha \mapsto|\alpha|$ for $\alpha \in K$ is an absolute value follows from $\operatorname{ord}_{\mathfrak{p}}$ being a valuation on $K$, and a $\mathfrak{p}$-adic absolute value on $K$ is nonarchimedean.

Changing $c$ produces an equivalent absolute value on $K$, so there is a well-defined $\mathfrak{p}$ adic topology on $K$ that independent of $c$. (This topology on the ring of integers $\mathcal{O}_{K}$
amounts to declaring the ideals $\mathfrak{p}^{k}$ to be a neighborhood basis of 0 in $\mathcal{O}_{K}$.) For two different nonzero prime ideals $\mathfrak{p}$ and $\mathfrak{q}$ in $\mathcal{O}_{K}$, a $\mathfrak{p}$-adic absolute value and $\mathfrak{q}$-adic absolute value are inequivalent: the Chinese remainder theorem lets us find $x \in \mathcal{O}_{K}$ satisfying $x \equiv 0 \bmod \mathfrak{p}$ and $x \equiv 1 \bmod \mathfrak{q}$, so the $\mathfrak{p}$-adic absolute value of $x$ is less than 1 and the $\mathfrak{q}$-adic absolute value of $x$ equals 1 . Thus the two absolute values are inequivalent.

Archimedean absolute values on $K$ are defined in terms of field embeddings $\sigma: K \rightarrow \mathbf{R}$ and $\sigma: K \rightarrow \mathbf{C}:|\alpha|:=|\sigma(\alpha)|_{\infty}$ where $|\cdot|_{\infty}$ is the standard absolute value on $\mathbf{R}$ or C. Letting $r_{1}$ be the number of real embedding of $K$ and $r_{2}$ be the number of pairs of complex-conjugate embeddings of $K$, there are $r_{1}+2 r_{2}$ archimedean embeddings of $K$ but only $r_{1}+r_{2}$ archimedean absolute values on $K$ (up to equivalence) since complex-conjugate embeddings define the same absolute value $\left(|a+b i|_{\infty}=|a-b i|_{\infty}\right.$ in $\left.\mathbf{C}\right)$ and the only way two archimedean embeddings of $K$ define the same absolute value is when they come from a pair of complex-conjugate embeddings; see [8, p. 42] for the proof of that.

Example 2.3. If $K$ is a real quadratic field then there are two real embeddings of $K$, so $K$ has two archimedean absolute values. For instance, on the abstract field $\mathbf{Q}(\theta)$ where $\theta^{2}=2$, the two archimedean absolute values are $|a+b \theta|=|a+b \sqrt{2}|$ and $|a+b \theta|=|a-b \sqrt{2}|$ for $a, b \in \mathbf{Q}$.

Example 2.4. If $K$ is an imaginary quadratic field then there are two complex embeddings of $K$ and they are complex-conjugate to each other, so $K$ has just one archimedean absolute value.

By tradition, the nonarchimedean absolute values on $K$ are called its finite absolute values while the archimedean absolute values on $K$ are called its infinite absolute values. This terminology is due to an analogy with the classification of nontrivial absolute values on $\mathbf{C}(z)$ that are trivial on $\mathbf{C}$ : they are associated to the different points on the Riemann sphere, by simply measuring the order of vanishing of a rational function at a point in the same way as a $p$-adic absolute value operates through a valuation function in the exponent. The absolute values on $\mathbf{C}(z)$ are bounded on $\mathbf{C}[z]$ except for the one associated to the order of vanishing at the point $\infty$ on the Riemann sphere. Since the archimedean absolute value on $\mathbf{Q}$ is the only one that is unbounded on $\mathbf{Z}$, by analogy one calls it an infinite absolute value. (This analogy is actually rather weak, since using a different field generator over $\mathbf{C}$, say $\mathbf{C}(w)$ where $w=1 / z$, changes which absolute value is "at infinity," whereas the archimedean absolute value on $\mathbf{Q}$ can't be turned into one of the $p$-adic ones by a field automorphism of $\mathbf{Q}$; in fact, the only field automorphism of $\mathbf{Q}$ is the identity.)

## 3. Classifying absolute values on $K$

Ostrowski's theorem for $K$ says every nontrivial absolute value on $K$ is equivalent to an absolute value on $K$ that we already described: a $\mathfrak{p}$-adic absolute value for a prime $\mathfrak{p}$ of $\mathcal{O}_{K}$ or an archimedean absolute value associated to a real or complex-conjugate pair of embeddings of $K$. When $K=\mathbf{Q}$, the proof of Ostrowki's theorem uses special features of $\mathcal{O}_{K}=\mathbf{Z}$ (like finite base expansions in $\mathbf{Z}^{+}$for the archimedean case and division with remainder in $\mathbf{Z}$ for the nonarchimedean case) that are not valid in number fields, so we need a different approach to prove the theorem for $K$.

Lemma 3.1. Let $\mathfrak{p}$ be a nonzero prime ideal in $\mathcal{O}_{K}$. If $\alpha \in K^{\times}$and $\operatorname{ord}_{\mathfrak{p}}(\alpha) \geq 0$ then $\alpha=x / y$ where $x$ and $y$ are in $\mathcal{O}_{K}$, are not 0 , and $\operatorname{ord}_{\mathfrak{p}}(y)=0$.

Proof. Write $\alpha \mathcal{O}_{K}=\mathfrak{a b}^{-1}$ for ideals $\mathfrak{a}$ and $\mathfrak{b}$ of $\mathcal{O}_{K}$ with no common factors. Because $\operatorname{ord}_{\mathfrak{p}}(\alpha) \geq 0, \mathfrak{p} \nmid \mathfrak{b}$. From $\mathfrak{a}=(\alpha) \mathfrak{b}, \mathfrak{a}$ and $\mathfrak{b}$ are in the same ideal class: $[\mathfrak{a}]=[\mathfrak{b}]$.

There is an integral ideal $\mathfrak{c}$ in $[\mathfrak{a}]^{-1}$ that is relatively prime to $\mathfrak{p}$ : pick $x \in \mathfrak{a}-\mathfrak{p a}$ and use $\mathfrak{c}=x \mathfrak{a}^{-1}$. This works because

- $\mathfrak{c}=x \mathfrak{a}^{-1} \Longrightarrow[\mathfrak{c}]=\left[\mathfrak{a}^{-1}\right]=[\mathfrak{a}]^{-1}$ in $\mathrm{Cl}(K)$,
- $x \in \mathfrak{a} \Longrightarrow \mathfrak{c}=x \mathfrak{a}^{-1} \subset \mathcal{O}_{K}$,
- if $\mathfrak{c}$ and $\mathfrak{p}$ are not relatively prime then $\mathfrak{p} \mid \mathfrak{c}$, so $\mathfrak{c} \subset \mathfrak{p}$, but having $x \mathfrak{a}^{-1} \subset \mathfrak{p}$ implies $x \in \mathfrak{p a}$, which contradicts the choice of $x .^{1}$
Then

$$
(\alpha)=\mathfrak{a} \mathfrak{b}^{-1}=\mathfrak{a c}(\mathfrak{b c})^{-1}
$$

and the ideals $\mathfrak{a c}$ and $\mathfrak{b c}$ are both principal, as $[\mathfrak{c}]=[\mathfrak{a}]^{-1}=[\mathfrak{b}]^{-1}$. We have $\mathfrak{a c}=(x)$. Set $\mathfrak{b c}=(y)$, so $x$ and $y$ are in $\mathcal{O}_{K}$ and not 0 . Since $\mathfrak{b}$ and $\mathfrak{c}$ are not divisible by $\mathfrak{p}, \operatorname{ord}_{\mathfrak{p}}(y)=0$. Now $(\alpha)=(x)(y)^{-1}=(x / y)$. Rescaling $x$ by a unit, $\alpha=x / y$ with $\operatorname{ord}_{\mathfrak{p}}(y)=0$.

The heart of the proof of the classification of nonarchimedean absolute values on $K$ is the next result.
Theorem 3.2. Let $v: K^{\times} \rightarrow \mathbf{R}$ be a nonzero homomorphism with

$$
\begin{equation*}
v(\alpha+\beta) \geq \min (v(\alpha), v(\beta)) \tag{3.1}
\end{equation*}
$$

when $\alpha, \beta$, and $\alpha+\beta$ are all in $K^{\times}$. Then $v=t \operatorname{ord}_{\mathfrak{p}}$ for a unique nonzero prime ideal $\mathfrak{p}$ and $t>0$.
Proof. Uniqueness is easy: For a nonzero prime ideal $\mathfrak{p}$,

$$
\left\{\alpha \in \mathcal{O}_{K}: t \operatorname{ord}_{\mathfrak{p}}(\alpha)>0\right\}=\left\{\alpha \in \mathcal{O}_{K}: \operatorname{ord}_{\mathfrak{p}}(\alpha)>0\right\}=\left\{\alpha \in \mathcal{O}_{K}: \alpha \in \mathfrak{p}\right\}=\mathfrak{p}
$$

That is, inside of $\mathcal{O}_{K}, t$ ord $_{\mathfrak{p}}$ takes positive values precisely on $\mathfrak{p}$, so we can recover $\mathfrak{p}$ from the properties of $t \operatorname{ord}_{\mathfrak{p}}$. Since $t$ is the smallest positive value of $t \operatorname{ord}_{\mathfrak{p}}$ on $K^{\times}$, the value of $t$ is determined as well.

As for the existence of a $\mathfrak{p}$ and $t$ such that $v=t$ ord $_{\mathfrak{p}}$, we will show that the set

$$
\begin{equation*}
\mathfrak{p}:=\left\{\alpha \in \mathcal{O}_{K}-\{0\}: v(\alpha)>0\right\} \cup\{0\} \tag{3.2}
\end{equation*}
$$

is a nonzero prime ideal in $\mathcal{O}_{K}$ and then we will show $v=t$ ord $_{\mathfrak{p}}$ for some $t>0$. Obviously this definition for $\mathfrak{p}$ is motivated by the calculation we made just before: if there is going to be a prime ideal for which $v$ is the corresponding valuation, the set in (3.2) has to be that ideal.

Before we even discuss $\mathfrak{p}$ in (3.2), we show $v(\alpha) \geq 0$ on all nonzero algebraic integers. Since $v(1 \cdot 1)=v(1)+v(1), v(1)=0$. Then $0=v(1)=v\left((-1)^{2}\right)=2 v(-1)$, so $v(-1)=0$. Now by (3.1), $v(a) \geq 0$ for all nonzero $a \in \mathbf{Z}$. In a sense, the nonnegativity of $v$ on $\mathbf{Z}-\{0\}$ underlies everything that follows. For $\alpha \in \mathcal{O}_{K}$, we can write an equation of integral dependence for it over $\mathbf{Z}$, say

$$
\alpha^{n}+a_{n-1} \alpha^{n-1}+\cdots+a_{1} \alpha+a_{0}=0
$$

with $a_{j} \in \mathbf{Z}$. Choose $n$ as small as possible, so $a_{0} \neq 0$. If $v(\alpha)<0$, then heuristically $\alpha^{n}$ has an $n$-th order pole at $v$, while the other terms in the sum on the left have a lower order pole (the $a_{j}$ 's don't contribute polar data since $v\left(a_{j}\right) \geq 0$ or $a_{j}=0$ ). Thus the whole sum on the left has a pole at $v$, but the sum is 0 , a contradiction.

[^0]For a rigorous argument, we rewrite the above equation as

$$
\alpha^{n}=-a_{n-1} \alpha^{n-1}-\cdots-a_{1} \alpha-a_{0} .
$$

When $a_{j} \neq 0, v\left(-a_{j} \alpha^{j}\right)=v\left(a_{j}\right)+j v(\alpha) \geq j v(\alpha)$. When $a_{j}=0$, of course the term $a_{j} \alpha^{j}$ is 0 so we ignore it. Now if $v(\alpha)<0$, then $v\left(-a_{j} \alpha^{j}\right) \geq(n-1) v(\alpha)$ since $j \leq n-1$. Therefore by (3.1) extended to a sum of several terms,

$$
v\left(-a_{n-1} \alpha^{n-1}-\cdots-a_{1} \alpha-a_{0}\right) \geq(n-1) v(\alpha) .
$$

Since $v\left(\alpha^{n}\right)=n v(\alpha)$, we have $n v(\alpha) \geq(n-1) v(\alpha)$, so $v(\alpha) \geq 0$. This contradicts the assumption that $v(\alpha)<0$. Therefore $v(\alpha) \geq 0$.

Since $v$ is not identically 0 on $K^{\times}$, it is not identically 0 on $\mathcal{O}_{K}-\{0\}$, which means $v$ must take some positive values on $\mathcal{O}_{K}-\{0\}$ (we just eliminated the possibility of negative values on $\left.\mathcal{O}_{K}-\{0\}\right)$. Thus the set $\mathfrak{p}$ in (3.2) is not $\{0\}$. Since $v$ is a homomorphism, easily $\mathfrak{p}$ is a subgroup of $\mathcal{O}_{K}$, and in fact an $\mathcal{O}_{K}$-module on account of the nonnegativity of $v$ on $\mathcal{O}_{K}-\{0\}$. So $\mathfrak{p}$ is an ideal in $\mathcal{O}_{K}$. Since $v(1)=0, \mathfrak{p}$ is a proper ideal of $\mathcal{O}_{K}$. Let's show it is a prime ideal. For $\alpha$ and $\beta$ in $\mathcal{O}_{K}$, assume $\alpha \beta \in \mathfrak{p}$. To show $\alpha$ or $\beta$ is in $\mathfrak{p}$, assume neither is in $\mathfrak{p}$. Then $v(\alpha)=0$ and $v(\beta)=0$, so $v(\alpha \beta)=v(\alpha)+v(\beta)=0$, but that contradicts $\alpha \beta$ being in $\mathfrak{p}$.

Now we have our nonzero prime ideal $\mathfrak{p}$, so it is time to show $v=t \operatorname{ord}_{\mathfrak{p}}$ for some $t$.
First we'll show that if $\operatorname{ord}_{\mathfrak{p}}(\alpha)=0$ then $v(\alpha)=0$. By Lemma 3.1 we can write $\alpha=x / y$ with $x, y \in \mathcal{O}_{K}$ and $\operatorname{ord}_{\mathfrak{p}}(y)=0$. Therefore $\operatorname{ord}_{\mathfrak{p}}(x)=\operatorname{ord}_{\mathfrak{p}}(\alpha y)=0+0=0$. Since $x$ and $y$ are in $\mathcal{O}_{K}$ and are not in $\mathfrak{p}$, the definition of $\mathfrak{p}$ tells us $v(x)=0$ and $v(y)=0$. Therefore $v(\alpha)=0$.

Now we show $v=t \operatorname{ord}_{\mathfrak{p}}$ for some $t>0$. For $\alpha \in K^{\times}$, let $n=\operatorname{ord}_{\mathfrak{p}}(\alpha) \in \mathbf{Z}$. Pick $\gamma \in \mathfrak{p}-\mathfrak{p}^{2}$, so $\operatorname{ord}_{\mathfrak{p}}(\gamma)=1$ and $v(\gamma)>0$. Then $\operatorname{ord}_{\mathfrak{p}}\left(\alpha / \gamma^{n}\right)=0$, so $v\left(\alpha / \gamma^{n}\right)=0$, so

$$
v(\alpha)=n v(\gamma)=\operatorname{ord}_{\mathfrak{p}}(\alpha) v(\gamma) .
$$

The choice of $\gamma$ has nothing to do with $\alpha$. This equation holds for all $\alpha \in K^{\times}$, so $v=t \operatorname{ord}_{\mathfrak{p}}$ where $t=v(\gamma)>0$.

Theorem 3.3. Each nontrivial absolute value on $K$ is equivalent to a $\mathfrak{p}$-adic absolute value for a unique prime $\mathfrak{p}$ in $\mathcal{O}_{K}$ or is equivalent to an absolute value coming from a real or complex embedding of $K$.

Proof. We treat separately nonarchimedean and archimedean absolute values on $K$. The first case was settled independently by Artin [1] (see also Ostrowski [7, Sect. 26]) while the second case is due to Ostrowski [6].

Case 1. $|\cdot|$ is a nonarchimedean absolute value on $K$.
We expect $|\cdot|$ to look like $\alpha \mapsto c^{\operatorname{ord}_{p}(\alpha)}$ for some $c \in(0,1)$, so the function $v(\alpha):=-\log |\alpha|$ should look like a positive scalar multiple of ord ${ }_{p}$. To prove this really happens, note $v$ satisfies the conditions of Theorem 3.2, so $-\log |\alpha|=t \operatorname{ord}_{\mathfrak{p}}(\alpha)$ for a unique $t>0$ and a unique nonzero prime ideal $\mathfrak{p}$ of $\mathcal{O}_{K}$. Rewriting this as $|\alpha|=\left(e^{-t}\right)^{\operatorname{ord}_{\mathfrak{p}}(\alpha)}$, we see $|\cdot|$ is a $\mathfrak{p}$-adic absolute value with constant $c=e^{-t}<1$.

Case 2. $|\cdot|$ is an archimedean absolute value on $K$.
The restriction of $|\cdot|$ to $\mathbf{Q}$ is an absolute value on $\mathbf{Q}$, and it can't be nonarchimedean since then $|\cdot|$ on $K$ would be nonarchimedean (an absolute value on $K$ is nonarchimedean if and only if $|n| \leq 1$ for all $n \in \mathbf{Z})$. Therefore $|\cdot|$ on $\mathbf{Q}$ is archimedean, so $|\cdot|$ on $\mathbf{Q}$ is equivalent to the standard absolute value $|\cdot|_{\infty}$ on $\mathbf{Q}:|r|=|r|_{\infty}^{t}$ for some $t>0$ and
all $r \in \mathbf{Q}$. We will show, following the argument in [2, pp. 278-280], that there is a field embedding $\sigma$ of $K$ into $\mathbf{R}$ or $\mathbf{C}$ such that $|\alpha|=|\sigma(\alpha)|_{\infty}^{t}$ for all $\alpha \in K$.

Let $\widehat{K}$ be the completion of $K$ with respect to $|\cdot|$, so $\widehat{K}$ is a field and $|\cdot|$ has an extension from $K$ to $\widehat{K}$, also to be denoted as $|\cdot|$, such that $\widehat{K}$ is complete with respect to $|\cdot|$ and $K$ is dense in $\widehat{K}$. The closure of $\mathbf{Q}$ in $\widehat{K}$ is a completion of $\mathbf{Q}$ with respect to $|\cdot|$, so we will denote it as $\widehat{\mathbf{Q}}$. Since $(\widehat{\mathbf{Q}},|\cdot|)$ and $\left(\mathbf{R},|\cdot|_{\infty}^{t}\right)$ are both completions of $(\mathbf{Q},|\cdot|)$, there is an isomorphism $\sigma: \widehat{\mathbf{Q}} \rightarrow \mathbf{R}$ of valued fields, as indicated in the field diagram below, so $|x|=|\sigma(x)|_{\infty}^{t}$ for all $x \in \widehat{\mathbf{Q}}$.

By the primitive element theorem, $K=\mathbf{Q}(\gamma)$ for some $\gamma$. If $\gamma \in \widehat{\mathbf{Q}}$ then $K \subset \widehat{\mathbf{Q}}$, so $|\alpha|=|\sigma(\alpha)|_{\infty}^{t}$ for all $\alpha \in K$. That shows $|\cdot|$ on $K$ comes from a real embedding of $K$. Also, since $\widehat{\mathbf{Q}}$ is complete and contains $K=\mathbf{Q}(\gamma)$, which is dense in $\widehat{K}$, we have $\widehat{K}=\widehat{\mathbf{Q}}$, so the embedding $K \hookrightarrow \widehat{K}$ is essentially a real embedding of $K$.

If $\gamma \notin \widehat{\mathbf{Q}}$ then the field $\widehat{\mathbf{Q}}(\gamma)$ is a finite extension of $\widehat{\mathbf{Q}}$ (since $\mathbf{Q}(\gamma)$ is a finite extension of $\mathbf{Q})$ with $[\widehat{\mathbf{Q}}(\gamma): \widehat{\mathbf{Q}}]>1$. Since $\mathbf{C}$ is algebraically closed, the only finite extension field of $\mathbf{R}$ other than $\mathbf{R}$ is $\mathbf{C}$, with degree 2 , so $[\widehat{\mathbf{Q}}(\gamma): \widehat{\mathbf{Q}}]=2$ and $\sigma: \widehat{\mathbf{Q}} \rightarrow \mathbf{R}$ can be extended in two ways to a field isomorphism $\tau: \widehat{\mathbf{Q}}(\gamma) \rightarrow \mathbf{C}$. Fix a choice of $\tau$. Since $\widehat{\mathbf{Q}}(\gamma) / \widehat{\mathbf{Q}}$ is a finite extension and $\widehat{\mathbf{Q}}$ is complete with respect to $|\cdot|, \widehat{\mathbf{Q}}(\gamma)$ is also complete with respect to $|\cdot|$. We have $K=\mathbf{Q}(\gamma) \subset \widehat{\mathbf{Q}}(\gamma) \subset \widehat{K}$ with $\widehat{K}$ complete and $K$ dense in $\widehat{K}$, so $\widehat{\mathbf{Q}}(\gamma)=\widehat{K}$. Therefore $\widehat{K} \cong \mathbf{C}$, so the completion of $K$ with respect to $|\cdot|$ is isomorphic to the complex numbers.

On the field $\widehat{\mathbf{Q}}(\gamma),|\cdot|$ and $x \mapsto|\tau(x)|_{\infty}^{t}$ are both absolute values extending $|\cdot|$ on $\widehat{\mathbf{Q}}$, so by the uniqueness of extending absolute values to finite extensions of complete fields we have $|x|=|\tau(x)|_{\infty}^{t}$ for all $x \in \widehat{K}$. This equation for $x \in K$ tells us $|\cdot|$ on $K$ comes from a complex embedding of $K$

Remark 3.4. Ostrowski [6], in the same paper where he classified the nontrivial absolute values on $\mathbf{Q}$, proved that a field complete with respect to an archimedean absolute value is isomorphic to $\mathbf{R}$ or $\mathbf{C}$. Proofs of this "other" Ostrowski theorem can be found in Jacobson [3, pp. 571-573], Lang [5, Chap. XII, Cor. 2.4], and Ribenboim [8, pp. 40-41]. Such a field must have characteristic 0 since absolute values in characteristic $p$ are always nonarchimedean, and the closure of $\mathbf{Q}$ in the field is a copy of $\mathbf{R}$, so Ostrowski's "other" theorem is basically saying that when $t$ is transcendental over $\mathbf{R}$ there is no extension of the standard absolute value on $\mathbf{R}$ to an absolute value on $\mathbf{R}(t)$.

## 4. Normalizing the absolute values on $K$

In Theorem 3.3, the descriptions of the nontrivial absolute values in the archimedean and non-archimedean cases look different: use real or complex embeddings in one case and use nonzero prime ideals in the other case. There is a way to describe both cases in a uniform way: consider field embeddings of $K$ into an algebraic closure of a completion of $\mathbf{Q}$ : embeddings of $K$ into $\overline{\mathbf{R}}=\mathbf{C}$ or $\overline{\mathbf{Q}}_{p}$ as $p$ varies. Embedding $K$ into such a field provides $K$ with a nontrivial absolute value by using the absolute value from $\mathbf{C}$ or $\overline{\mathbf{Q}}_{p}$ on the image of $K$ under the embedding. Every nontrivial absolute value on $K$ arises in this way (proof?), but it is not quite true that different embeddings of $K$ into some $\overline{\mathbf{Q}}_{v}(v=\infty$ or $p$ ) produce different absolute values on $K$. For instance, we have already noted that in the archimedean setting complex-conjugate embeddings of $K$ into $\mathbf{C}$ define the same absolute value on $K$. A similar thing can happen $p$-adically. As an example, the two embeddings $\mathbf{Q}(i) \rightarrow \overline{\mathbf{Q}}_{2}$, obtained by sending $i$ to the two different square roots of -1 in $\mathbf{Q}_{2}$, define the same absolute value on $\mathbf{Q}(i)$. Similarly, the two embeddings $\mathbf{Q}(i) \rightarrow \overline{\mathbf{Q}}_{3}$ give $\mathbf{Q}(i)$ the same absolute value. However, the two embeddings $\mathbf{Q}(i) \rightarrow \overline{\mathbf{Q}}_{5}$ define different absolute values. To describe which embeddings of $K$ into some $\overline{\mathbf{Q}}_{v}$ define the same absolute value on $K$, see [4, Theorem 2, p. 38] (setting $K=\mathbf{Q}$ there).

The standard nontrivial absolute values on $\mathbf{Q}$ are tied together by a product formula. This generalizes to $K$ if we normalize the absolute values on $K$ in the right way. Here's how that is done. For a nonzero prime ideal $\mathfrak{p}$ in $\mathcal{O}_{K}$, use $1 / \mathrm{Np}$ as the base for the $\mathfrak{p}$-adic absolute value:

$$
|\alpha|_{\mathfrak{p}}=\left(\frac{1}{\mathrm{~N} \mathfrak{p}}\right)^{\operatorname{ord}_{\mathfrak{p}}(\alpha)}
$$

for $\alpha \in K^{\times}$. For the archimedean absolute values on $K$, we use the absolute values from every real embedding and the squares of the absolute values from the complex-conjugate pairs of complex embeddings. ${ }^{2}$ We have now selected one absolute value on $K$ from every nontrivial equivalence class, with a peculiar twist in the complex case of using the square of the absolute value.

[^1]Theorem 4.1 (Product Formula). For $\alpha \neq 0$ in $K$,

$$
\prod_{v}|\alpha|_{v}=1
$$

where the product runs over the absolute values on $K$ as described above.
Example 4.2. Take $K=\mathbf{Q}(i)$ and $\alpha=3+i=-i(1+i)(1+2 i)$. Then $|\alpha|_{\infty}^{2}=|3+i|^{2}=$ $3^{2}+1^{2}=10,|\alpha|_{1+i}=1 / 2,|\alpha|_{1+2 i}=1 / 5$, and $|\alpha|_{v}=1$ for all other absolute values on $\mathbf{Q}(i)$. Then $\prod_{v}|\alpha|_{v}=10(1 / 2)(1 / 5)=1$.

For each $\alpha \in K$, all but finitely many $|\alpha|_{v}$ are 1 , so the formally infinite product of $|\alpha|_{v}$ over all $v$ in Theorem 4.1 is a finite product, and thus the product makes sense algebraically.

Proof. The product is multiplicative in $\alpha$, so it suffices to check the product formula when $\alpha \in \mathcal{O}_{K}-\{0\}$.

Case 1: $\alpha \in \mathcal{O}_{K}^{\times}$. Here $|\alpha|_{\mathfrak{p}}=1$ for all $\mathfrak{p}$. For archimedean $v$ that correspond to a real embedding $\sigma: K \rightarrow \mathbf{R},|\alpha|_{v}=|\sigma(\alpha)|$. For archimedean $v$ that correspond to a complex embedding $\sigma: K \rightarrow \mathbf{C},|\alpha|_{v}=|\sigma(\alpha)|^{2}=|\sigma(\alpha)||\bar{\sigma}(\alpha)|$. Therefore

$$
\prod_{v}|\alpha|_{v}=\prod_{\text {arch. } v}|\alpha|_{v}=\prod_{\text {real } \sigma}|\sigma(\alpha)| \prod_{\text {cpx. } \sigma}|\sigma(\alpha)||\bar{\sigma}(\alpha)|=\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right|
$$

since the product of the absolute values of $\alpha$ under all real and complex embeddings of $K$, where we count pairs of conjugate embeddings separately, is $\mathrm{N}_{K / \mathbf{Q}}(\alpha)$. (Specifically, if $\sigma: K \rightarrow \mathbf{C}$ is a complex embedding of $K$ then $|\sigma(\alpha)|^{2}=|\sigma(\alpha)||\bar{\sigma}(\alpha)|$ can be interpreted as a contribution to $\prod_{v}|\alpha|_{v}$ from both $\sigma$ and $\bar{\sigma}$ rather than being a "double" contribution from $\sigma$.) Since $\alpha \in \mathcal{O}_{K}^{\times}, \mathrm{N}_{K / \mathbf{Q}}(\alpha)= \pm 1$, so $\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right|=1$.

Case 2: $\alpha \notin \mathcal{O}_{K}^{\times}$. The ideal $\alpha \mathcal{O}_{K}$ is a proper ideal. Factor it into prime ideals:

$$
\alpha \mathcal{O}_{K}=\mathfrak{p}_{1}^{a_{1}} \cdots \mathfrak{p}_{r}^{a_{r}},
$$

where $a_{j} \geq 1$. The only terms in $\prod_{v}|\alpha|_{v}$ that are not necessarily 1 come from the absolute values on $K$ attached to $\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{r}$ and to the archimedean absolute values on $K$. We separately treat the contribution from non-archimedean and archimedean absolute values.

The contribution to $\prod_{v}|\alpha|_{v}$ from $\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{r}$ is

$$
\prod_{j=1}^{r}\left(\frac{1}{\mathrm{~Np}_{j}}\right)^{a_{j}}
$$

As in Case 1, the archimedean contribution to $\prod_{v}|\alpha|_{v}$ is $\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right|$. From the compatibility of the norm on elements and on principal ideals,

$$
\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right|=\mathrm{N}\left(\alpha \mathcal{O}_{K}\right)=\prod_{j=1}^{r} \mathrm{~Np}_{j}^{a_{j}},
$$

which means the archimedean and non-archimedean contributions to $\prod_{v}|\alpha|_{v}$ are inverses of each other, so their product is 1 .

Remark 4.3. It was not really necessary to treat separately the cases $\alpha \in \mathcal{O}_{K}^{\times}$and $\alpha \notin \mathcal{O}_{K}^{\times}$ in the proof: Case 2 is applicable to $\alpha \in \mathcal{O}_{K}^{\times}$by relaxing the exponent constraint $a_{j} \geq 1$ to $a_{j} \geq 0$.

The use of squared complex absolute values doesn't just make the product formula work out, but appears in many other situations in algebraic number theory.

There is a second way to prove the product formula. Collect together the factors in the product for absolute values on $K$ that extend a given absolute value on $\mathbf{Q}$ and see what these subproducts turn out to be:

$$
\prod_{v}|\alpha|_{v}=\prod_{v \mid \infty}|\alpha|_{v} \cdot \prod_{p} \prod_{\mathfrak{p} \mid p}|\alpha|_{\mathfrak{p}}
$$

where we write $v \mid \infty$ to mean $v$ is an archimedean absolute value on $K$ and it is understood that we use the squares of absolute values from complex embeddings. The product of the archimedean absolute values is $\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right|$, which we used in the proof above. For each prime number $p$ it turns out that $\prod_{\mathfrak{p} \mid p}|\alpha|_{\mathfrak{p}}=\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right|_{p}$. Therefore

$$
\begin{equation*}
\prod_{v}|\alpha|_{v}=\left|\mathrm{N}_{K / \mathbf{Q}}(\alpha)\right| \cdot \prod_{p}\left|\mathrm{~N}_{K / \mathbf{Q}}(\alpha)\right|_{p} \tag{4.1}
\end{equation*}
$$

so the product formula for $\alpha$ as an element of $K$ turns into the product formula for $\mathrm{N}_{K / \mathbf{Q}}(\alpha)$ as a rational number. Therefore if we already know the product formula over $\mathbf{Q}$, then the right side of (4.1) is 1 , which proves the product formula over $K$ !

In addition to number fields, we should consider the function field case. That is, we should allow $K$ to be a finite extension of $\mathbf{F}_{p}(T)$, where $T$ is transcendental over $\mathbf{F}_{p}$. (Equivalently, $K$ has transcendence degree 1 over $\mathbf{F}_{p}$ and the algebraic closure of $\mathbf{F}_{p}$ in $K$ is a finite extension of $\mathbf{F}_{p}$.) We know what the nontrivial absolute values are on $\mathbf{F}_{p}(T)$; they are associated to the monic irreducibles in $\mathbf{F}_{p}[T]$ and to the negative degree function. Each of these lifts to absolute values on $K$ in terms of nonzero prime ideals (there are no archimedean absolute values in characteristic $p$ ), but trying to think of these prime ideals as lying in some "ring of integers" is awkward because there is no canonical ring of integers in $K$, essentially since there isn't one in $\mathbf{F}_{p}(T)$ either, e.g., $\mathbf{F}_{p}[T]$ could be replaced with $\mathbf{F}_{p}[1 / T]$. Using a geometric language, one can think of elements of $K$ as certain functions on a smooth curve, and the absolute values on $K$ (or rather, the associated valuations on $K$ ) turn out to be the order-of-vanishing functions at points on this curve. The main argument one needs in this development is an analogue of Theorem 3.2.

## Appendix A. Ideal class representative relatively prime to an ideal

In the proof of Lemma 3.1 we showed that for a nonzero prime ideal $\mathfrak{p}$ in $\mathcal{O}_{K}$, each ideal class in $\mathrm{Cl}(K)$ contains an integral ideal not divisible by $\mathfrak{p}$. Below is a generalization that replaces $\mathfrak{p}$ with other ideals in $\mathcal{O}_{K}$.

Theorem A.1. Let $\mathfrak{n}$ be a nonzero ideal in $\mathcal{O}_{K}$. Each ideal class in $\mathrm{Cl}(K)$ has a representative that is an ideal in $\mathcal{O}_{K}$ and is relatively prime to $\mathfrak{n}$.

Proof. This is trivial if $\mathfrak{n}=(1)$, so assume $\mathfrak{n} \neq(1)$.
We will give two proofs.
First proof. Pick an ideal class in $\mathrm{Cl}(K)$. It can be written as $[\mathfrak{a}]^{-1}$ where $\mathfrak{a}$ is integral.
$\overline{\text { Let }} \mathfrak{p}_{1}, \ldots, \mathfrak{p}_{r}$ be all the prime ideals dividing $\mathfrak{a}$ or $\mathfrak{n}$. Write

$$
\mathfrak{a}=\mathfrak{p}_{1}^{e_{1}} \cdots \mathfrak{p}_{r}^{e_{r}}, \quad e_{i} \geq 0
$$

For $1 \leq i \leq r$, pick $x_{i} \in \mathfrak{p}_{i}^{e_{i}}-\mathfrak{p}_{i}^{e_{i}+1}$, so $\mathfrak{p}_{i}^{e_{i}} \mid\left(x_{i}\right)$ and $\mathfrak{p}_{i}^{e_{i}+1} \nmid\left(x_{i}\right)$. Thus $\mathfrak{p}_{i}^{e_{i}} \|\left(x_{i}\right)$. (The double bars mean this power of $\mathfrak{p}_{i}$ is a factor and no higher one is.) By the Chinese remainder
theorem, there exists $x \in \mathcal{O}_{K}$ such that

$$
x \equiv x_{i} \bmod \mathfrak{p}_{i}^{e_{i}+1}
$$

for all $i$, so $x \in \mathfrak{p}_{i}^{e_{i}}-\mathfrak{p}_{i}^{e_{i}+1}$. Thus $\mathfrak{p}_{i}^{e_{i}} \|(x)$ for all $i$, so the prime factorization of $(x)$ is

$$
(x)=\mathfrak{p}_{1}^{e_{1}} \cdots \mathfrak{p}_{r}^{e_{r}} \mathfrak{b}=\mathfrak{a b}
$$

for some ideal $\mathfrak{b}$ in $\mathcal{O}_{K}$ not divisible by any $\mathfrak{p}_{i}$. Hence $\mathfrak{b} \in[\mathfrak{a}]^{-1}$ and $\mathfrak{b}+\mathfrak{n}=(1)$.
Second proof. I thank Will Sawin for the following argument.
Pick an ideal class in $\mathrm{Cl}(K)$ and write it as $[\mathfrak{a}]^{-1}$ where $\mathfrak{a}$ is integral. We want to find an $x \in K^{\times}$such that
(i) $x \mathfrak{a}^{-1} \subset \mathcal{O}_{K}$,
(ii) $x \mathfrak{a}^{-1}+\mathfrak{n}=\mathcal{O}_{K}$.

Condition (i) says $x \in \mathfrak{a}$ and condition (ii) implies $x \neq 0$, so $\mathfrak{b}:=x \mathfrak{a}^{-1}$ is an ideal in $\mathcal{O}_{K}$ such that $\mathfrak{b} \in[\mathfrak{a}]^{-1}$ and $\mathfrak{b}+\mathfrak{n}=(1)$.

Let $\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{r}$ be the different prime ideal factors of $\mathfrak{n}$. For each $x \in \mathfrak{a}$,
$\mathfrak{n} \subset x \mathfrak{a}^{-1}+\mathfrak{n} \subset \mathcal{O}_{K}$.
If $x \mathfrak{a}^{-1}+\mathfrak{n}=\mathcal{O}_{K}$ then $x$ fits (i) and (ii), so we are done. If $x \mathfrak{a}^{-1}+\mathfrak{n} \neq \mathcal{O}_{K}$, then $x \mathfrak{a}^{-1}+\mathfrak{n}$ is contained in a maximal ideal of $\mathcal{O}_{K}$, which is some $\mathfrak{p}_{i}$ by (A.1). Since $\mathfrak{n} \subset \mathfrak{p}_{i}$, from $x \mathfrak{a}^{-1}+\mathfrak{n} \subset \mathfrak{p}_{i}$ we get $x \mathfrak{a}^{-1} \subset \mathfrak{p}_{i}$, so $x \in \mathfrak{p}_{i} \mathfrak{a}$. So as long as we can choose an $x \in \mathfrak{a}$ such that $x \notin \mathfrak{p}_{i} \mathfrak{a}$ for $i=1, \ldots, r$, that $x$ fits (i) and (ii), so we're done.

For $1 \leq i \leq r, \mathfrak{p}_{i} \mathfrak{a}$ is strictly smaller than $\mathfrak{a}$. Pick $x_{i} \in \mathfrak{a}-\mathfrak{p}_{i} \mathfrak{a}$ for each $i$. If we can find $x \in \mathfrak{a}$ such that $x \equiv x_{i} \bmod \mathfrak{p}_{i} \mathfrak{a}$ for all $i$, then $x \notin \mathfrak{p}_{i} \mathfrak{a}$ for $i=1, \ldots, r$, so this $x$ would fit (i) and (ii) by the previous paragraph. Existence of such $x$ follows from the mapping

$$
\begin{equation*}
\mathfrak{a} \longrightarrow \prod_{i=1}^{r} \mathfrak{a} / \mathfrak{p}_{i} \mathfrak{a} \tag{A.2}
\end{equation*}
$$

where $x \mapsto\left(x \bmod \mathfrak{p}_{1} \mathfrak{a}, \ldots, x \bmod \mathfrak{p}_{r} \mathfrak{a}\right)$ being onto. This is part of the Chinese remainder theorem for modules, ${ }^{3}$ but we'll give a direct proof of surjectivity in our setting.

To prove (A.2) is surjective it is enough to show for each $y_{j} \in \mathfrak{a}$ that in $\mathfrak{a}$ we can solve

$$
\begin{equation*}
y \equiv y_{j} \bmod \mathfrak{p}_{j} \mathfrak{a} \text { and } y \equiv 0 \bmod \mathfrak{p}_{i} \mathfrak{a} \text { for } i \neq j \tag{A.3}
\end{equation*}
$$

Let $\mathfrak{b}_{j}=\prod_{i \neq j} \mathfrak{p}_{i}$, so $\mathfrak{p}_{j}+\mathfrak{b}_{j}=(1)$. Thus $1=\alpha_{j}+\beta_{j}$ where $\alpha_{j} \in \mathfrak{p}_{j}$ and $\beta_{j} \in \mathfrak{b}_{j}$. Since $\beta_{j} \equiv$ $1 \bmod \mathfrak{p}_{j}$ and $\beta_{j} \equiv 0 \bmod \mathfrak{b}_{j}, y:=y_{j} \beta_{j}$ satisfies $y \equiv y_{j} \bmod \mathfrak{p}_{j} \mathfrak{a}$ and $y \equiv 0 \bmod \mathfrak{b}_{j} \mathfrak{a}$.

[^0]:    ${ }^{1}$ More generally, for each nonzero ideal $\mathfrak{n}$ in $\mathcal{O}_{K}$, each ideal class in $\mathrm{Cl}(K)$ contains an integral ideal relatively prime to $\mathfrak{n}$. A proof is in Theorem A.1.

[^1]:    ${ }^{2}$ Strictly speaking, $|z|^{2}$ on $\mathbf{C}$ is not an absolute value, but for the purpose of getting a product formula it is convenient to treat it as one. In place of the triangle inequality, since $|z+w| \leq 2 \max (|z|,|w|)$ we have $|z+w|^{2} \leq 4 \max \left(|z|^{2},|w|\right)^{2}$.
