# CHARACTERS OF FINITE ABELIAN GROUPS (SHORT VERSION) 

KEITH CONRAD

## 1. Introduction

The theme we will study is an analogue on finite abelian groups of Fourier analysis on $\mathbf{R}$. A Fourier series on the real line is the following type of series in sines and cosines:

$$
f(x)=\sum_{n \geq 0} a_{n} \cos (n x)+\sum_{n \geq 1} b_{n} \sin (n x) .
$$

This is $2 \pi$-periodic. Since $e^{i n x}=\cos (n x)+i \sin (n x)$ and $e^{-i n x}=\cos (n x)-i \sin (n x)$, a Fourier series can also be written in terms of complex exponentials:

$$
f(x)=\sum_{n \in \mathbf{Z}} c_{n} e^{i n x},
$$

where $c_{0}=a_{0}, c_{n}=\frac{1}{2}\left(a_{n}-b_{n} i\right)$ for $n>0$, and $c_{n}=\frac{1}{2}\left(a_{|n|}+b_{|n|} i\right)$ for $n<0$. The convenient algebraic property of $e^{i n x}$, not shared by sines and cosines, is that it is a group homomorphism from $\mathbf{R}$ to the unit circle $S^{1}=\{z \in \mathbf{C}:|z|=1\}$ :

$$
e^{i n\left(x+x^{\prime}\right)}=e^{i n x} e^{i n x^{\prime}}
$$

We now replace $\mathbf{R}$ with a finite abelian group. Here is the analogue of the functions $e^{i n x}$.
Definition 1.1. A character of a finite abelian group $G$ is a homomorphism $\chi: G \rightarrow S^{1}$.
We will usually write abstract groups multiplicatively, so $\chi\left(g_{1} g_{2}\right)=\chi\left(g_{1}\right) \chi\left(g_{2}\right)$ and $\chi(1)=1$.
Example 1.2. The trivial character of $G$ is the homomorphism $\mathbf{1}_{G}$ defined by $\mathbf{1}_{G}(g)=1$ for all $g \in G$.
Example 1.3. Let $G$ be cyclic of order 4 with generator $\gamma$. Since $\gamma^{4}=1$, a character $\chi$ of $G$ has $\chi(\gamma)^{4}=1$, so $\chi$ takes only four possible values at $\gamma$, namely $1,-1, i$, or $-i$. Once $\chi(\gamma)$ is known, the value of $\chi$ elsewhere is determined by multiplicativity: $\chi\left(\gamma^{j}\right)=\chi(\gamma)^{j}$. So we get four characters, whose values can be placed in a table. See Table 1.

|  | 1 | $\gamma$ | $\gamma^{2}$ | $\gamma^{3}$ |
| ---: | ---: | ---: | ---: | ---: |
| $\mathbf{1}_{G}$ | 1 | 1 | 1 | 1 |
| $\chi_{1}$ | 1 | -1 | 1 | -1 |
| $\chi_{2}$ | 1 | $i$ | -1 | $-i$ |
| $\chi_{3}$ | 1 | $-i$ | -1 | $i$ |
|  | TABLE |  |  | 1. |

When $G$ has size $n$ and $g \in G$, for all characters $\chi$ of $G$ we have $\chi(g)^{n}=\chi\left(g^{n}\right)=\chi(1)=1$, so the values of $\chi$ lie among the $n$th roots of unity in $S^{1}$. More precisely, the order of $\chi(g)$ divides the order of $g$ (which divides $|G|$ ).

Characters on finite abelian groups were first studied in number theory, which is a source of many interesting finite abelian groups. For instance, Dirichlet used characters of the group $(\mathbf{Z} /(m))^{\times}$to prove that when $(a, m)=1$ there are infinitely many primes $p \equiv a \bmod m$. The quadratic reciprocity law of elementary number theory is concerned with a deep property of a particular character, the Legendre symbol. Fourier series on finite abelian groups have applications in engineering: signal processing (the fast Fourier transform [1, Chap. 9]) and error-correcting codes [1, Chap. 11].

To provide a context against which our development of characters on finite abelian groups can be compared, Section 2 discusses classical Fourier analysis on the real line. In Section 3 we discuss some properties of characters of finite abelian groups and introduce their dual groups. Section 4 uses characters of a finite abelian group to develop a finite analogue of Fourier series. In Section 5 we use characters to prove a structure theorem for finite abelian groups. In Section 6 we use characters to count solutions to a congruence mod $p$.

Our notation is completely standard, but we make two remarks about it. For a complexvalued function $f(x)$, the complex-conjugate function is usually denoted $\bar{f}(x)$ instead of $\overline{f(x)}$ to stress that conjugation creates a new function. (We sometimes use the overline notation also to mean the reduction $\bar{g}$ into a quotient group.) For $n \geq 1$, we write $\mu_{n}$ for the group of $n$th roots of unity in the unit circle $S^{1}$. It is a cyclic group of size $n$.

## Exercises.

1. Make a character table for $\mathbf{Z} /(2) \times \mathbf{Z} /(2)$, with columns labeled by elements of the group and rows labeled by characters, as in Table 1.
2. Let $G$ be a finite nonabelian simple group. (Examples include $A_{n}$ for $n \geq 5$.) Show the only group homomorphism $\chi: G \rightarrow S^{1}$ is the trivial map.

## 2. Classical Fourier analysis

This section serves as motivation for our later treatment of finite abelian groups, where there will be no convergence issues (just finite sums!), so we take a soft approach and sidestep analytic technicalities that a serious treatment of Fourier analysis on $\mathbf{R}$ demands.

Fourier analysis for periodic functions on $\mathbf{R}$ is based on the functions $e^{i n x}$ for $n \in \mathbf{Z}$. Every "reasonably nice" function $f: \mathbf{R} \rightarrow \mathbf{C}$ of period $2 \pi$ can be expanded into a series

$$
f(x)=\sum_{n \in \mathbf{Z}} c_{n} e^{i n x},
$$

where the sum runs over $\mathbf{Z}$ and the $n$th Fourier coefficient $c_{n}$ can be recovered as an integral:

$$
\begin{equation*}
c_{n}=\frac{1}{2 \pi} \int_{0}^{2 \pi} f(x) e^{-i n x} \mathrm{~d} x \tag{2.1}
\end{equation*}
$$

This formula for $c_{n}$ can be explained by replacing $f(x)$ in (2.1) by its Fourier series and integrating termwise (for "reasonably nice" functions this termwise integration is analytically justifiable), using the formula

$$
\frac{1}{2 \pi} \int_{0}^{2 \pi} e^{i m x} e^{-i n x} \mathrm{~d} x= \begin{cases}1, & \text { if } m=n \\ 0, & \text { if } m \neq n\end{cases}
$$

Rather than working with functions $f: \mathbf{R} \rightarrow \mathbf{C}$ having period $2 \pi$, formulas look cleaner using functions $f: \mathbf{R} \rightarrow \mathbf{C}$ having period 1. The basic exponentials become $e^{2 \pi i n x}$ and the Fourier series and coefficients for $f$ are

$$
\begin{equation*}
f(x)=\sum_{n \in \mathbf{Z}} c_{n} e^{2 \pi i n x}, \quad c_{n}=\int_{0}^{1} f(x) e^{-2 \pi i n x} \mathrm{~d} x . \tag{2.2}
\end{equation*}
$$

Note $c_{n}$ in (2.2) is not the same as $c_{n}$ in (2.1).
In addition to Fourier series there are Fourier integrals. The Fourier transform of a function $f$ that decays rapidly at $\pm \infty$ is the function $\widehat{f}: \mathbf{R} \rightarrow \mathbf{C}$ defined by the integral formula

$$
\widehat{f}(y)=\int_{\mathbf{R}} f(x) e^{-2 \pi i x y} \mathrm{~d} x .
$$

The analogue of the expansion (2.2) of a periodic function into a Fourier series is the Fourier inversion formula, which expresses $f$ in terms of its Fourier transform $\widehat{f}$ :

$$
f(x)=\int_{\mathbf{R}} \widehat{f}(y) e^{2 \pi i x y} \mathrm{~d} y .
$$

Example 2.1. A Gaussian is a function of the form $a e^{-b x^{2}}$, where $b>0$. For example, the Gaussian $(1 / \sqrt{2 \pi}) e^{-(1 / 2) x^{2}}$ is important in probability theory. The Fourier transform of a Gaussian is another Gaussian:

$$
\begin{equation*}
\int_{\mathbf{R}} a e^{-b x^{2}} e^{-2 \pi i x y} \mathrm{~d} x=\sqrt{\frac{\pi}{b}} a e^{-\pi^{2} y^{2} / b} . \tag{2.3}
\end{equation*}
$$

This formula shows that a highly peaked Gaussian (large b) has a Fourier transform that is a spread out Gaussian (small $\pi^{2} / b$ ) and vice versa. More generally, there is a sense in which a function and its Fourier transform can't both be highly localized; this is a mathematical incarnation of Heisenberg's uncertainty principle from physics.

There are several conventions for where $2 \pi$ appears in the Fourier transform. Table 2 collects three different $2 \pi$-conventions. The first column of Table 2 is a definition and the second column is a theorem (Fourier inversion).

$$
\begin{array}{cc}
\widehat{f}(y) & f(x) \\
\hline \int_{\mathbf{R}} f(x) e^{-2 \pi i x y} \mathrm{~d} x & \int_{\mathbf{R}} \widehat{f}(y) e^{2 \pi i x y} \mathrm{~d} y \\
\int_{\mathbf{R}} f(x) e^{-i x y} \mathrm{~d} x & \frac{1}{2 \pi} \int_{\mathbf{R}} \widehat{f}(y) e^{i x y} \mathrm{~d} y \\
\frac{1}{\sqrt{2 \pi}} \int_{\mathbf{R}} f(x) e^{-i x y} \mathrm{~d} x & \frac{1}{\sqrt{2 \pi}} \int_{\mathbf{R}} \widehat{f}(y) e^{i x y} \mathrm{~d} y
\end{array}
$$

Table 2.

A link between Fourier series and Fourier integrals is the Poisson summation formula: for a "nice" function $f: \mathbf{R} \rightarrow \mathbf{C}$ that decays rapidly enough at $\pm \infty$,

$$
\begin{equation*}
\sum_{n \in \mathbf{Z}} f(n)=\sum_{n \in \mathbf{Z}} \widehat{f}(n), \tag{2.4}
\end{equation*}
$$

where $\widehat{f}(y)=\int_{\mathbf{R}} f(x) e^{-2 \pi i x y} \mathrm{~d} x$. For example, when $f(x)=e^{-b x^{2}}$ (with $b>0$ ), the Poisson summation formula says

$$
\sum_{n \in \mathbf{Z}} e^{-b n^{2}}=\sum_{n \in \mathbf{Z}} \sqrt{\frac{\pi}{b}} e^{-\pi^{2} n^{2} / b}
$$

To prove the Poisson summation formula, we use Fourier series. Periodize $f(x)$ as

$$
F(x)=\sum_{n \in \mathbf{Z}} f(x+n) .
$$

Since $F(x+1)=F(x)$, write $F$ as a Fourier series: $F(x)=\sum_{n \in \mathbf{Z}} c_{n} e^{2 \pi i n x}$. Then

$$
\begin{aligned}
c_{n} & =\int_{0}^{1} F(x) e^{-2 \pi i n x} \mathrm{~d} x \\
& =\int_{0}^{1}\left(\sum_{m \in \mathbf{Z}} f(x+m)\right) e^{-2 \pi i n x} \mathrm{~d} x \\
& =\sum_{m \in \mathbf{Z}} \int_{0}^{1} f(x+m) e^{-2 \pi i n x} \mathrm{~d} x \\
& =\sum_{m \in \mathbf{Z}} \int_{m}^{m+1} f(x) e^{-2 \pi i n x} \mathrm{~d} x \\
& =\int_{\mathbf{R}} f(x) e^{-2 \pi i n x} \mathrm{~d} x \\
& =\widehat{f}(n)
\end{aligned}
$$

Therefore the expansion of $F(x)$ into a Fourier series is equivalent to

$$
\begin{equation*}
\sum_{n \in \mathbf{Z}} f(x+n)=\sum_{n \in \mathbf{Z}} \widehat{f}(n) e^{2 \pi i n x} \tag{2.5}
\end{equation*}
$$

which becomes the Poisson summation formula (2.4) by setting $x=0$.
Exercises.

1. Without dwelling on analytic subtleties, check from Fourier inversion that $\widehat{\hat{f}}(x)=$ $f(-x)$ (if the Fourier transform is defined suitably).
2. For a function $f: \mathbf{R} \rightarrow \mathbf{C}$ and $c \in \mathbf{R}$, let $g(x)=f(x+c)$. Define the Fourier transform of a function $h$ by $\widehat{h}(y)=\int_{\mathbf{R}} h(x) e^{-2 \pi i x y} \mathrm{~d} x$. If $f$ has a Fourier transform, show $g$ has Fourier transform $\widehat{g}(y)=e^{2 \pi i c y} \widehat{f}(y)$.
3. Assuming the Fourier inversion formula holds for a definition of the Fourier transform as in Table 2, check that for all $\alpha$ and $\beta$ in $\mathbf{R}^{\times}$that if we set

$$
(\mathcal{F} f)(y)=\alpha \int_{\mathbf{R}} f(x) e^{-i \beta x y} \mathrm{~d} x
$$

for all $x$ then

$$
f(x)=\frac{\beta}{2 \pi \alpha} \int_{\mathbf{R}}(\mathcal{F} f)(y) e^{i \beta x y} \mathrm{~d} y
$$

(If $\beta=2 \pi \alpha^{2}$ then these two equations are symmetric in the roles of $f$ and $\mathcal{F} f$ except for a sign in the exponential term.)

## 3. Finite Abelian Group Characters

We leave the real line and turn to the setting of finite abelian groups $G$. Our interest shifts from the functions $e^{i n x}$ to characters: homomorphisms from $G \rightarrow S^{1}$. The construction of characters of these groups begins with the case of cyclic groups.
Theorem 3.1. Let $G$ be a finite cyclic group of size $n$ with a chosen generator $\gamma$. There are exactly $n$ characters of $G$, each determined by sending $\gamma$ to the different nth roots of unity in $\mathbf{C}$.
Proof. We mimic Example 1.3, where $G$ is cyclic of size 4. Since $\gamma$ generates $G$, a character is determined by its value on $\gamma$ and that value must be an $n$th root of unity (not necessarily of exact order $n$, e.g., $\mathbf{1}_{G}(\gamma)=1$ ), so there are at most $n$ characters. We now write down $n$ characters.

Let $\zeta$ be an $n$th root of unity in $\mathbf{C}$. Set $\chi\left(\gamma^{j}\right)=\zeta^{j}$ for $j \in \mathbf{Z}$. This formula is well-defined (if $\gamma^{j}=\gamma^{k}$ for two different integer exponents $j$ and $k$, we have $j \equiv k \bmod n$ so $\zeta^{j}=\zeta^{k}$ ), and $\chi$ is a homomorphism. Of course $\chi$ depends on $\zeta$. As $\zeta$ changes, we get different characters (their values at $\gamma$ are changing), so in total we have $n$ characters.

To handle characters of non-cyclic groups, the following lemma is critical.
Lemma 3.2. Let $G$ be a finite abelian group, $H \subset G$ a proper subgroup, and $\chi: H \rightarrow S^{1} a$ character of $H$. For $g \in G-H$, there is an extension of $\chi$ to a character on $\langle H, g\rangle$.
Proof. We want to extend $\chi$ to a character $\widetilde{\chi}$ of $\langle H, g\rangle$.
What is a possible value for $\widetilde{\chi}(g)$ ? Since $g \notin H, \widetilde{\chi}(g)$ is not initially defined. But some nonzero power of $g$ is in $H$ (e.g., $g^{|G|}=1 \in H$ ), and on these powers $\chi$ is defined. Pick $d \geq 1$ minimal with $g^{d} \in H$. That is, $d$ is the order of $g$ in $G / H$, so $d=[\langle H, g\rangle: H]$. If there is a character $\widetilde{\chi}$ on $\langle, H, g$ that extends $\chi$ on $H$ then $\widetilde{\chi}(g)$ must be an $d$-th root of $\chi\left(g^{d}\right)$ since we must have $\widetilde{\chi}(g)^{d}=\widetilde{\chi}\left(g^{d}\right)=\chi\left(g^{d}\right)$. That is our clue: define $\widetilde{\chi}(g) \in S^{1}$ to be a solution to $z^{d}=\chi\left(g^{d}\right)$ :

$$
\begin{equation*}
\widetilde{\chi}(g)^{d}=\chi\left(g^{d}\right) . \tag{3.1}
\end{equation*}
$$

Once we have chosen $\widetilde{\chi}(g)$ to satisfy (3.1), define $\widetilde{\chi}$ on $\langle H, g\rangle$ by

$$
\begin{equation*}
\widetilde{\chi}\left(h g^{i}\right):=\chi(h) \widetilde{\chi}(g)^{i} . \tag{3.2}
\end{equation*}
$$

This formula covers all possible elements of $\langle H, g\rangle$, but is $\widetilde{\chi}$ well-defined? Perhaps $H$ and $\langle g\rangle$ overlap nontrivially, so the expression of an element of $\langle H, g\rangle$ in the form $h g^{i}$ is not unique. We have to show this doesn't lead to an inconsistency in the value of $\widetilde{\chi}$ in (3.2). Suppose $h g^{i}=h^{\prime} g^{i^{\prime}}$. Then $g^{i-i^{\prime}} \in H$, so $i^{\prime} \equiv i \bmod d$ since $d$ is the order of $g$ in $G / H$. Write $i^{\prime}=i+d d^{\prime}$, so $h=h^{\prime} a^{i^{\prime}-i}=h^{\prime} g^{d d^{\prime}}$. The terms $h, h^{\prime}$, and $g^{d}$ are in $H$, so

$$
\begin{aligned}
\chi\left(h^{\prime}\right) \widetilde{\chi}(g)^{i^{\prime}} & =\chi\left(h^{\prime}\right) \widetilde{\chi}(g)^{i} \widetilde{\chi}(g)^{d d^{\prime}} \\
& =\chi\left(h^{\prime}\right) \widetilde{\chi}(g)^{i} \chi\left(g^{d}\right)^{d^{\prime}} \text { since } \widetilde{\chi}(g)^{d}=\chi\left(g^{d}\right) \\
& =\chi\left(h^{\prime} g^{d d^{\prime}}\right) \widetilde{\chi}(g)^{i} \\
& =\chi(h) \widetilde{\chi}(g)^{i} .
\end{aligned}
$$

Therefore $\widetilde{\chi}:\langle H, g\rangle \rightarrow S^{1}$ is a well-defined function and it is easily checked to be a homomorphism. It restricts to $\chi$ on $H$.
Theorem 3.3. For a finite abelian group $G$ and subgroup $H$, each character of $H$ can be extended to a character of $G$.

Proof. Let $\chi: H \rightarrow S^{1}$ be a character of $H$.
Since $G$ is finite, it has a finite generating set $\left\{g_{1}, \ldots, g_{k}\right\}$ (e.g., $\left\{g_{i}\right\}$ could be a listing of all the elements of $G$ ). Therefore we can build up a tower of subgroups from $H$ to $G$ by adjoining the elements $g_{i}$ one at a time:

$$
H \subset\left\langle H, g_{1}\right\rangle \subset\left\langle H, g_{1}, g_{2}\right\rangle \subset \cdots \subset\left\langle H, g_{1}, \ldots, g_{k}\right\rangle=G .
$$

Each step along this tower has the form $H_{i} \subset\left\langle H_{i}, g_{i}\right\rangle$, where $H_{0}=H$. By applying Lemma 3.2 at each step of the tower, $\chi$ can be extended as a character from $H$ to $H_{1}$ to $H_{2}$, and so on up to $H_{k}=G$.

Let's refine this to count the number of extensions of a character from $H$ to $G$.
Theorem 3.4. For a finite abelian group $G$ and subgroup $H$, each character of $H$ can be extended to a character of $G$ in $[G: H]$ ways.

Proof. We will induct on the index $[G: H]$. The result is clear when $[G: H]=1$, i.e., $H=G$, so suppose $[G: H]>1$ and the theorem is proved for characters on subgroups of index smaller than $[G: H]$.

Pick $g \in G$ with $g \notin H$, so

$$
H \subset\langle H, g\rangle \subset G .
$$

To extend a character $\chi: H \rightarrow S^{1}$ to $G$, we at least need to be able to extend $\chi$ to a character $\widetilde{\chi}$ on $\langle H, g\rangle$. Let's count the number of ways to do that. Then we will use induction to count the number of extension of each character from $\langle H, g\rangle$ all the way up to $G$.

Let $d$ be the smallest positive integer such that $g^{d} \in H$. An extension of $\chi$ on $H$ to a character $\widetilde{\chi}$ on $\langle H, g\rangle$ is determined by $\widetilde{\chi}(g)$, and this value has to satisfy the condition $\widetilde{\chi}(g)^{d}=\chi\left(g^{d}\right)$. Each number in $S^{1}$ has $d$ different $d$-th roots in $S^{1}$, so there are $d$ potential values for $\widetilde{\chi}(g)$. The proof of Lemma 3.2 shows all of them really work.

The number of choices of $\widetilde{\chi}$ extending $\chi$ is the number of choices for $\widetilde{\chi}(g)$, which is $d=[\langle H, g\rangle: H]$. Since $[G:\langle H, g\rangle]<[G: H]$, by induction on the index there are $[G:\langle H, g\rangle]$ extensions of each $\widetilde{\chi}$ to a character of $G$, so the number of extensions of a character on $H$ to a character on $G$ is $[G:\langle H, g\rangle][\langle H, g\rangle: H]=[G: H]$.

Theorem 3.5. If $g \neq 1$ in a finite abelian group $G$ then $\chi(g) \neq 1$ for some character $\chi$ of $G$. The number of characters of $G$ is $|G|$.

Proof. The cyclic group $\langle g\rangle$ is nontrivial, say of size $n$, so $n>1$. In $S^{1}$ there is a cyclic subgroup of order $n$, namely the group $\mu_{n}$ of $n$-th roots of unity. There is an isomorphism $\langle g\rangle \cong \mu_{n}$, which can be viewed as a character of $\langle g\rangle$. By Theorem 3.3, this character of $\langle g\rangle$ extends to a character of $G$ and does not send $g$ to 1 .

To show $G$ has $|G|$ characters, apply Theorem 3.4 with $H$ the trivial subgroup.
We have used two important features of $S^{1}$ as the target group for characters: for each $d \geq 1$ the $d$ th power map on $S^{1}$ is $d$-to- 1 (proof of Theorem 3.4) and for each $n \geq 1$ there is a cyclic subgroup of order $n$ in $S^{1}$ (proof of Theorem 3.5).

Corollary 3.6. If $G$ is a finite abelian group and $g_{1} \neq g_{2}$ in $G$ then there is a character of $G$ that takes different values at $g_{1}$ and $g_{2}$.
Proof. Apply Theorem 3.5 to $g=g_{1} g_{2}^{-1}$.
Corollary 3.6 shows the characters of $G$ "separate" the elements of $G$ : different elements of the group admit a character taking different values on them.

Corollary 3.7. If $G$ is a finite abelian group and $H \subset G$ is a subgroup and $g \in G$ with $g \notin H$ then there is a character of $G$ that is trivial on $H$ and not equal to 1 at $g$.
Proof. We work in the group $G / H$, where $\bar{g} \neq \overline{1}$. By Theorem 3.5 there is a character of $G / H$ that is not 1 at $\bar{g}$. Composing this character with the reduction map $G \rightarrow G / H$ yields a character of $G$ that is trivial on $H$ and not equal to 1 at $g$.

It is easy to find functions on $G$ that separate elements without using characters. For $g \in G$, define $\delta_{g}: G \rightarrow\{0,1\}$ by

$$
\delta_{g}(x)= \begin{cases}1, & \text { if } x=g  \tag{3.3}\\ 0, & \text { if } x \neq g\end{cases}
$$

These functions separate elements of the group, but characters do this too and have better algebraic properties: they are group homomorphisms.

Our definition of a character makes sense on nonabelian groups, but there will not be enough such characters for Theorem 3.5 to hold if $G$ is finite and nonabelian: a homomorphism $\chi: G \rightarrow S^{1}$ must equal 1 on the commutator subgroup $[G, G]$, which is a nontrivial subgroup, so such homomorphisms can't distinguish elements in $[G, G]$ from each other. If $g \notin[G, G]$ then in the finite abelian group $G /[G, G]$ the coset of $g$ is nontrivial so there is a character $G /[G, G] \rightarrow S^{1}$ that's nontrivial on $\bar{g}$. Composing this character with the reduction map $G \rightarrow G /[G, G]$ produces a homomorphism $G \rightarrow S^{1}$ that is nontrivial on $g$.
Definition 3.8. For a character $\chi$ on a finite abelian group $G$, the conjugate character is the function $\bar{\chi}: G \rightarrow S^{1}$ given by $\bar{\chi}(g):=\overline{\chi(g)}$.

Since a complex number $z$ with $|z|=1$ has $\bar{z}=1 / z, \bar{\chi}(g)=\chi(g)^{-1}=\chi\left(g^{-1}\right)$.
Definition 3.9. The dual group of a finite abelian group $G$ is the set of homomorphisms $G \rightarrow S^{1}$ with the group law of pointwise multiplication of functions: $(\chi \psi)(g)=\chi(g) \psi(g)$. The dual group of $G$ is denoted $\widehat{G}$.

The trivial character of $G$ is the identity in $\widehat{G}$ and the inverse of a character is its conjugate character. Note $\widehat{G}$ is abelian since multiplication in $\mathbf{C}^{\times}$is commutative.

Theorem 3.5 says in part that

$$
\begin{equation*}
|G|=|\widehat{G}| . \tag{3.4}
\end{equation*}
$$

In fact, the groups $G$ and $\widehat{G}$ are isomorphic. First let's check this on cyclic groups.
Theorem 3.10. If $G$ is cyclic then $G \cong \widehat{G}$ as groups.
Proof. We will show $\widehat{G}$ is cyclic. Then since $G$ and $\widehat{G}$ have the same size they are isomorphic.
Let $n=|G|$ and $\gamma$ be a generator of $G$. Set $\chi: G \rightarrow S^{1}$ by $\chi\left(\gamma^{j}\right)=e^{2 \pi i j / n}$ for all $j$. For other characters $\psi \in \widehat{G}$, we have $\psi(\gamma)=e^{2 \pi i k / n}$ for some integer $k$, so $\psi(\gamma)=\chi(\gamma)^{k}$. Then

$$
\psi\left(\gamma^{j}\right)=\psi(\gamma)^{j}=\chi(\gamma)^{j k}=\chi\left(\gamma^{j}\right)^{k},
$$

which shows $\psi=\chi^{k}$. Therefore $\chi$ generates $\widehat{G}$.
Lemma 3.11. If $A$ and $B$ are finite abelian groups, there is an isomorphism $\widehat{A \times B} \cong \widehat{A} \times \widehat{B}$.
Proof. Let $\chi$ be a character on $A \times B$. Identify the subgroups $A \times\{1\}$ and $\{1\} \times B$ of $A \times B$ with $A$ and $B$ in the obvious way. Let $\chi_{A}$ and $\chi_{B}$ be the restrictions of $\chi$ to $A$ and
$B$ respectively, i.e., $\chi_{A}(a)=\chi(a, 1)$ and $\chi_{B}(b)=\chi(1, b)$. Then $\chi_{A}$ and $\chi_{B}$ are characters of $A$ and $B$ and $\chi(a, b)=\chi((a, 1)(1, b))=\chi(a, 1) \chi(1, b)=\chi_{A}(a) \chi_{B}(b)$. So we get a map

$$
\begin{equation*}
\widehat{A \times B} \rightarrow \widehat{A} \times \widehat{B} \tag{3.5}
\end{equation*}
$$

by sending $\chi$ to $\left(\chi_{A}, \chi_{B}\right)$. It is left to the reader to check (3.5) is a group homomorphism. Its kernel is trivial since if $\chi_{A}$ and $\chi_{B}$ are trivial characters then $\chi(a, b)=\chi_{A}(a) \chi_{B}(b)=1$, so $\chi$ is trivial. Both sides of (3.5) have the same size by (3.4), so (3.5) is an isomorphism.
Theorem 3.12. If $G$ is a finite abelian group then $G$ is isomorphic to $\widehat{G}$.
Proof. The case when $G$ is cyclic was Theorem 3.10. Lemma 3.11 extends easily to several factors in a direct product:

$$
\begin{equation*}
\left(H_{1} \times \cdots \times H_{r}\right)^{\wedge} \cong \widehat{H}_{1} \times \cdots \times \widehat{H}_{r} . \tag{3.6}
\end{equation*}
$$

When $H_{i}$ is cyclic, $\widehat{H}_{i} \cong H_{i}$, so (3.6) tells us that that character group of $H_{1} \times \cdots \times H_{r}$ is isomorphic to itself. Every finite abelian group is isomorphic to a direct product of cyclic groups, so the character group of a finite abelian group is isomorphic to itself.

Although $G$ and $\widehat{G}$ are isomorphic groups, there is not a natural isomorphism between them, even when $G$ is cyclic. For instance, to prove $G \cong \widehat{G}$ when $G$ is cyclic we had to choose a generator. If we change the generator, then the isomorphism changes. ${ }^{1}$

The double-dual group $\widehat{\widehat{G}}$ is the dual group of $\widehat{G}$. Since $G$ and $\widehat{G}$ are isomorphic, $G$ and $\widehat{\widehat{G}}$ are isomorphic. However, while there isn't a natural isomorphism from $G$ to $\widehat{G}$, there is a natural isomorphism from $G$ to $\widehat{\widehat{G}}$. The point is that there is a natural way to map $G$ to its double-dual group: associate to each $g \in G$ the function "evaluate at $g$," which is the function $\widehat{G} \rightarrow S^{1}$ given by $\chi \mapsto \chi(g)$. Here $g$ is fixed and $\chi$ varies. This is a character of $\widehat{G}$, since $\left(\chi_{1} \chi_{2}\right)(g)=\chi_{1}(g) \chi_{2}(g)$ by definition.

Theorem 3.13. Let $G$ be a finite abelian group. The homomorphism $G \rightarrow \widehat{\widehat{G}}$ associating to $g \in G$ the function "evaluate at $g$ " is an isomorphism.

Proof. Since a finite abelian group and its dual group have the same size, a group and its double-dual group have the same size, so it suffices to show this homomorphism is injective. If $g \in G$ is in the kernel then every element of $\widehat{G}$ is 1 at $g$, so $g=1$ by Theorem 3.5.

Theorem 3.13 is called Pontryagin duality. This label actually applies to a more general result about characters of locally compact abelian groups. Finite abelian groups are a special case, where difficult analytic techniques can be replaced by counting arguments. The isomorphism between $G$ and its double-dual group given by Pontryagin duality lets us think about a finite abelian group $G$ as a dual group (namely the dual group of $\widehat{G}$ ).

The isomorphism in Pontryagin duality is natural: it does not depend on ad hoc choices (unlike the isomorphism between a finite abelian group and its dual group).
Exercises.

[^0]1. Let's find the characters of the additive group $(\mathbf{Z} /(m))^{r}$, an $r$-fold direct product.
(a) For $k \in \mathbf{Z} /(m)$, let $\chi_{k}: \mathbf{Z} /(m) \rightarrow S^{1}$ by

$$
\chi_{k}(j)=e^{2 \pi i j k / m}
$$

so $\chi_{k}(1)=e^{2 \pi i k / m}$. Show $\chi_{0}, \chi_{1}, \ldots, \chi_{m-1}$ are all the characters of $\mathbf{Z} /(m)$ and $\chi_{k} \chi_{l}=\chi_{k+l}$.
(b) Let $r \geq 1$. For $r$-tuples $\mathbf{a}, \mathbf{b}$ in $(\mathbf{Z} /(m))^{r}$, let

$$
\mathbf{a} \cdot \mathbf{b}=a_{1} b_{1}+\cdots+a_{r} b_{r} \in \mathbf{Z} /(m)
$$

be the usual dot product. For $\mathbf{k} \in(\mathbf{Z} /(m))^{r}$, let $\chi_{\mathbf{k}}(\mathbf{j})=e^{2 \pi i(\mathbf{j} \cdot \mathbf{k}) / m}$. Show the functions $\chi_{\mathbf{k}}$ are all the characters of $(\mathbf{Z} /(m))^{r}$ and $\chi_{\mathbf{k}} \chi_{\mathbf{l}}=\chi_{\mathbf{k}+1}$.
2. Show the following are equivalent properties of a character $\chi: \chi(g)= \pm 1$ for all $g$, $\bar{\chi}(g)=\chi(g)$ for all $g$, and $\chi^{2}=\mathbf{1}_{G}$.
3. Describe the error in the following bogus proof of Theorem 3.4. Let $m=[G: H]$ and pick a set of coset representatives $g_{1}, \ldots, g_{m}$ for $G / H$. Given a character $\chi$ on $H$, define $\widetilde{\chi}$ on $G$ by first picking the $m(=[G: H])$ values $\widetilde{\chi}\left(g_{i}\right)$ for $1 \leq i \leq m$ and then writing each $g \in G$ in the (unique) form $g_{i} h$ and defining $\widetilde{\chi}(g)=\widetilde{\chi}\left(g_{i}\right) \chi(h)$. This defines $\widehat{\chi}$ on $G$, and since we had to make $m$ choices there are $m$ characters.
4. For finite nonabelian $G$, show the characters of $G$ (that is, homomorphisms $G \rightarrow S^{1}$ ) separate elements modulo $[G, G]: \chi\left(g_{1}\right)=\chi\left(g_{2}\right)$ for all $\chi$ if and only if $g_{1}=g_{2}$ in $G /[G, G]$.
5. This exercise will give an interpretation of characters as eigenvectors. For a finite abelian group $G$ and $g \in G$, let $T_{g}: L(G) \rightarrow L(G)$ by $\left(T_{g} f\right)(x)=f(g x)$.
(a) Show the $T_{g}$ 's are commuting linear transformations and each character of $G$ is an eigenvector of each $T_{g}$.
(b) If $f$ is a simultaneous eigenvector of all the $T_{g}$ 's, show $f(1) \neq 0$ (if $f(1)=0$ conclude $f$ is identically zero, but the zero vector is not an eigenvector) and then after rescaling $f$ so $f(1)=1$ deduce that $f$ is a character of $G$. Thus the characters of $G$ are the simultaneous eigenvectors of the $T_{g}$ 's, suitably normalized.
(c) Show the $T_{g}$ 's are each diagonalizable. Deduce from this and parts (a) and (b) that $\widehat{G}$ is a basis of $L(G)$, so $|\widehat{G}|=\operatorname{dim} L(G)=|G|$. (This gives a different proof that $G$ and $\widehat{G}$ have the same size.)
6. For a subgroup $H$ of a finite abelian group $G$, let

$$
H^{\perp}=\{\chi \in \widehat{G}: \chi=1 \text { on } H\} .
$$

These are the characters of $G$ that are trivial on $H$. For example, $G^{\perp}=\left\{\mathbf{1}_{G}\right\}$ and $\{1\}^{\perp}=\widehat{G}$. Note $H^{\perp} \subset \widehat{G}$ and $H^{\perp}$ depends on $H$ and $G$.

Show $H^{\perp}$ is a subgroup of $\widehat{G}$, it is isomorphic to $\widehat{G / H}$, and $\widehat{G} /\left(H^{\perp}\right) \cong \widehat{H}$. In particular, $\left|H^{\perp}\right|=[G: H]$.
7. Let $G$ be finite abelian and $H \subset G$ be a subgroup.
(a) Viewing $H^{\perp \perp}=\left(H^{\perp}\right)^{\perp}$ in $G$ using Pontryagin duality, show $H^{\perp \perp}=H$. (Hint: The inclusion in one direction is easy. Count sizes for the other inclusion.)
(b) Show for each $m$ dividing $|G|$ that

$$
|\{H \subset G:|H|=m\}=|\{H \subset G:[G: H]=m\}|
$$

by associating $H$ to $H^{\perp}$ and using a (fixed) isomorphism of $G$ with $\widehat{G}$.
(c) For a finite abelian group $G$, part b says the number of subgroups of $G$ with index 2 is equal to the number of elements of $G$ with order 2 . Use this idea to count the number of subgroups of $(\mathbf{Z} /(m))^{\times}$with index 2 . (The answer depends on the number of odd prime factors of $m$ and the highest power of 2 dividing $m$.)
(d) Show, for a prime $p$, that the number of subspaces of $(\mathbf{Z} /(p))^{n}$ with dimension $d$ equals the number of subspaces with dimension $n-d$.
8. For a finite abelian group $G$, let $G[n]=\left\{g \in G: g^{n}=1\right\}$ and $G^{n}=\left\{g^{n}: g \in G\right\}$. Both are subgroups of $G$. Prove $G[n]^{\perp}=(\widehat{G})^{n}$ and $\left(G^{n}\right)^{\perp}=\widehat{G}[n]$ in $\widehat{G}$.

## 4. Finite Fourier series

Let $G$ be a finite abelian group. Set

$$
L(G)=\{f: G \rightarrow \mathbf{C}\},
$$

the $\mathbf{C}$-valued functions on $G$. This is a $\mathbf{C}$-vector space of functions. Every $f \in L(G)$ can be expressed as a linear combination of the delta-functions $\delta_{g}$ from (3.3):

$$
\begin{equation*}
f=\sum_{g \in G} f(g) \delta_{g} . \tag{4.1}
\end{equation*}
$$

Indeed, evaluate both sides at each $x \in G$ and we get the same value. The functions $\delta_{g}$ span $L(G)$ by (4.1) and they are linearly independent: if $\sum_{g} a_{g} \delta_{g}=0$ then evaluating the sum at $x \in G$ shows $a_{x}=0$. Thus the functions $\delta_{g}$ are a basis of $L(G)$, so $\operatorname{dim} L(G)=|G|$.

The next theorem is the first step leading to an expression for each $\delta_{g}$ as a linear combination of characters of $G$, which will lead to a Fourier series expansion of $f$. It is the first time we add character values.
Theorem 4.1. Let $G$ be a finite abelian group. Then

$$
\sum_{g \in G} \chi(g)=\left\{\begin{array}{cl}
|G|, & \text { if } \chi=\mathbf{1}_{G}, \\
0, & \text { if } \chi \neq \mathbf{1}_{G},
\end{array} \quad \sum_{\chi \in \widehat{G}} \chi(g)=\left\{\begin{array}{cl}
|G|, & \text { if } g=1, \\
0, & \text { if } g \neq 1 .
\end{array}\right.\right.
$$

Proof. Let $S=\sum_{g \in G} \chi(g)$. If $\chi$ is trivial on $G$ then $S=|G|$. If $\chi$ is not trivial on $G$, say $\chi\left(g_{0}\right) \neq 1$. Then $\chi\left(g_{0}\right) S=\sum_{g \in G} \chi\left(g g_{0}\right)=\sum_{g \in G} \chi(g)=S$, so $S=0$.

The second formula in the theorem can be viewed as an instance of the first formula via Pontryagin duality: the second sum is a sum of the character "evaluate at $g$ " over the group $\widehat{G}$, and this character on $\widehat{G}$ is nontrivial when $g \neq 1$ by Pontryagin duality.

Theorem 4.1 says the sum of a nontrivial character over a group vanishes and the sum of all characters of a group evaluated at a nontrivial element vanishes, so the sum of the elements in each row and column of a character table of $G$ is zero except the row for the trivial character and the column for the identity element. Check this in Table 1.
Corollary 4.2. For characters $\chi_{1}$ and $\chi_{2}$ in $\widehat{G}$ and $g_{1}$ and $g_{2}$ in $G$,

$$
\sum_{g \in G} \chi_{1}(g) \bar{\chi}_{2}(g)=\left\{\begin{array}{cl}
|G|, & \text { if } \chi_{1}=\chi_{2}, \\
0, & \text { if } \chi_{1} \neq \chi_{2},
\end{array} \quad \sum_{\chi \in \widehat{G}} \chi\left(g_{1}\right) \bar{\chi}\left(g_{2}\right)=\left\{\begin{array}{cl}
|G|, & \text { if } g_{1}=g_{2} \\
0, & \text { if } g_{1} \neq g_{2}
\end{array}\right.\right.
$$

Proof. In the first equation of Theorem 4.1 let $\chi=\chi_{1} \bar{\chi}_{2}$. In the second equation of Theorem 4.1 let $g=g_{1} g_{2}^{-1}$. (Alternatively, after proving the first equation for all $G$ we observe that the second equation is a special case of the first by Pontryagin duality.)

The equations in Corollary 4.2 are called the orthogonality relations. They say that the character table of $G$ has orthogonal rows and orthogonal columns when we define orthogonality of two $n$-tuples of complex numbers as vanishing of their Hermitian inner product in $\mathbf{C}^{n}:\left\langle\left(z_{1}, \ldots, z_{n}\right),\left(w_{1}, \ldots, w_{n}\right)\right\rangle:=\sum_{k=1}^{n} z_{k} \overline{w_{k}}$.

By the second equation in Corollary 4.2 we can express the delta-functions in terms of characters:

$$
\sum_{\chi \in \widehat{G}} \chi(g) \bar{\chi}(x)=|G| \delta_{g}(x) \Longrightarrow \delta_{g}(x)=\frac{1}{|G|} \sum_{\chi \in \widehat{G}} \bar{\chi}(g) \chi(x) .
$$

Substituting this formula for $\delta_{g}$ into (4.1) gives

$$
\begin{align*}
f(x) & =\sum_{g \in G} f(g)\left(\frac{1}{|G|} \sum_{\chi \in \widehat{G}} \bar{\chi}(g) \chi(x)\right) \\
& =\sum_{\chi \in \widehat{G}} \sum_{g \in G} \frac{1}{|G|} f(g) \bar{\chi}(g) \chi(x) \\
& =\sum_{\chi \in \widehat{G}} c_{\chi} \chi(x), \tag{4.2}
\end{align*}
$$

where

$$
\begin{equation*}
c_{\chi}=\frac{1}{|G|} \sum_{g \in G} f(g) \bar{\chi}(g) . \tag{4.3}
\end{equation*}
$$

The expansion (4.2) is the Fourier series for $f$.
Equation (4.3) is similar to the formula for the coefficient $c_{n}$ of $e^{i n x}$ in (2.1): an integral over $[0,2 \pi]$ divided by $2 \pi$ is replaced by a sum over $G$ divided by $|G|$ and $f(x) e^{-i n x}$ is replaced by $f(g) \bar{\chi}(g)$. The number $e^{-i n x}$ is the conjugate of $e^{i n x}$, which is also the relation between $\bar{\chi}(g)$ and $\chi(g)$. Equation (4.2) shows $\widehat{G}$ is a spanning set for $L(G)$. Since $|\widehat{G}|=$ $|G|=\operatorname{dim} L(G), \widehat{G}$ is a basis for $L(G)$.
Definition 4.3. Let $G$ be a finite abelian group. If $f \in L(G)$ then its Fourier transform is the function $\widehat{f} \in L(\widehat{G})$ given by

$$
\widehat{f}(\chi)=\sum_{g \in G} f(g) \bar{\chi}(g) .
$$

By (4.2) and (4.3),

$$
\begin{equation*}
f(x)=\frac{1}{|G|} \sum_{\chi \in \widehat{G}} \widehat{f}(\chi) \chi(x) . \tag{4.4}
\end{equation*}
$$

Equation (4.4) is called the Fourier inversion formula since it tells us how to recover $f$ from its Fourier transform.

Remark 4.4. Classically the Fourier transform of a function $\mathbf{R} \rightarrow \mathbf{C}$ is another function $\mathbf{R} \rightarrow \mathbf{C}$. The finite Fourier transform, however, is defined on the dual group instead of on the original group. We can also interpret the classical Fourier transform to be a function of characters. For $y \in \mathbf{R}$ let $\chi_{y}(x)=e^{i x y}$. Then $\chi_{y}: \mathbf{R} \rightarrow S^{1}$ is a character and $\widehat{f}(y)$ could be viewed as $\widehat{f}\left(\chi_{y}\right)=\int_{\mathbf{R}} f(x) \bar{\chi}_{y}(x) \mathrm{d} x$, so $\widehat{f}$ is a function of characters rather than of numbers.

Example 4.5. Let $f=\delta_{g}$. Then $\widehat{f}(\chi)=\bar{\chi}(g)=\chi\left(g^{-1}\right)$.
Let's look at Fourier transforms for functions on a cyclic group. By writing a cyclic group in the form $\mathbf{Z} /(m)$, we can make an isomorphism with the dual group explicit: every character of $\mathbf{Z} /(m)$ has the form $\chi_{k}: j \mapsto e^{2 \pi i j k / m}$ for a unique $k \in \mathbf{Z} /(m)$ (Exercise 3.1). The Fourier transform of a function $f: \mathbf{Z} /(m) \rightarrow \mathbf{C}$ can be viewed as a function on $\mathbf{Z} /(m)$ :

$$
\begin{equation*}
\widehat{f}(k):=\sum_{j \in \mathbf{Z} /(m)} f(j) \overline{\chi k}(j)=\sum_{j \in \mathbf{Z} /(m)} f(j) e^{-2 \pi i j k / m} . \tag{4.5}
\end{equation*}
$$

This is like viewing the Fourier transform of a function on $\mathbf{R}$ as a function of $\mathbf{R}$.
Example 4.6. Let $f: \mathbf{Z} /(8) \rightarrow \mathbf{C}$ have the periodic values 5, 3, 1 , and 1 . Both $f$ and its Fourier transform are in Table 3. This $f$ has frequency 2 (its period repeats twice) and the Fourier transform vanishes except at $0,2,4$, and 6 , which are multiples of the frequency.

| $n$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $f(n)$ | 5 | 3 | 1 | 1 | 5 | 3 | 1 | 1 |
| $\widehat{f}(n)$ | 20 | 0 | $8+4 i$ | 0 | 4 | 0 | $8-4 i$ | 0 |

Table 3.

Example 4.7. Consider a function $f: \mathbf{Z} /(45) \rightarrow \mathbf{C}$ with the four successive repeating values $1,8,19,17$ starting with $f(0)=1$. It is not a periodic function on $\mathbf{Z} /(45)$ since 4 does not divide 45 , but the sequence $1,8,19,17$ repeats nearly 11 times. (The value of $f(44)$ is 1.) A calculation of $|\widehat{f}(n)|$, the absolute value of the Fourier transform of $f$, reveals sharp peaks at $n=0,11,22,23$, and 34 . See a plot of $|\widehat{f}(n)|$ below.

The red peaks are cut off because the lowest red bar would be around three times as tall as the highest black bar. Peaks in $|\widehat{f}(n)|$ occur approximately at multiples of the approximate frequency!

As Example 4.6 suggests, the Fourier transform of a periodic function on $\mathbf{Z} /(m)$ knows the frequency of the original function by the positions where the Fourier transform has nonzero values (Exercise 4.2). For nearly periodic functions on $\mathbf{Z} /(m)$, the approximate frequency is reflected in where the Fourier transform takes on its largest values. This idea is used in Shor's quantum algorithm for integer factorization [2], [3, Chap. 17].

Exercises.

1. Let $f: \mathbf{Z} /(8) \rightarrow \mathbf{C}$ take the four values $a, b, c$, and $d$ twice in this order. Compute $\widehat{f}(n)$ explicitly and determine some values for $a, b, c$, and $d$ such that $\widehat{f}(n)$ is nonzero for $n=0,2$, and 6 , but $\widehat{f}(4)=0$.
2. Let $H$ be a subgroup of a finite abelian group $G$.
(a) Suppose $f: G \rightarrow \mathbf{C}$ is constant on $H$-cosets (it is $H$-periodic). For $\chi \in \widehat{G}$ with $\chi \notin H^{\perp}$, show $\widehat{f}(\chi)=0$. Thus the Fourier transform of an $H$-periodic function on $G$ is supported on $H^{\perp}$.
(b) If $f: \mathbf{Z} /(m) \rightarrow \mathbf{C}$ has period $d$ where $d \mid m$, show $\widehat{f}: \mathbf{Z} /(m) \rightarrow \mathbf{C}$ is supported on the multiples of $m / d$. (See Example 4.6.)
3. Let $f: G \rightarrow \mathbf{C}$.
a) Show $f(g) \in \mathbf{R}$ for all $g$ if and only if $\overline{\hat{f}(\chi)}=\widehat{f}(\bar{\chi})$ for all $\chi$.
b) Show $\widehat{f}(\chi) \in \mathbf{R}$ for all $\chi$ if and only if $\overline{f(g)}=f\left(g^{-1}\right)$ for all $g$.
4. Let $G$ be a finite abelian group and $H$ be a subgroup. For a function $f: G \rightarrow \mathbf{C}$, Poisson summation on $G$ says

$$
\frac{1}{|H|} \sum_{h \in H} f(h)=\frac{1}{|G|} \sum_{\chi \in H^{\perp}} \widehat{f}(\chi),
$$

where $H^{\perp}$ is as in Exercise 3.6. Prove this formula in two ways:
a) Copy the classical proof sketched in Section 2 (start with the function $F(x)=$ $\sum_{h \in H} f(x h)$, which is $H$-periodic so it defines a function on $\left.G / H\right)$ to obtain

$$
\frac{1}{|H|} \sum_{h \in H} f(x h)=\frac{1}{|G|} \sum_{\chi \in H^{\perp}} \widehat{f}(\chi) \chi(x)
$$

for all $x \in G$ and then set $x=1$.
b) By linearity in $f$ of both sides of the desired identity, verify Poisson summation directly on the delta-functions of $G$. (Corollary 3.7 and Example 4.5 will be useful.)

## 5. Structure of finite abelian groups

We will now put characters to work by using them to prove each finite abelian group is a direct product of cyclic groups. This result was used in the proof of Theorem 3.12, that $G \cong \widehat{G}$, but that work will not be used here, so no circular reasoning occurs.

The following theorem shows that every cyclic subgroup of maximal size in a finite abelian group can be split off as a direct factor. Characters get used in an essential way in the proof.

Theorem 5.1. Let $G$ be a finite abelian group and let $g \in G$ have maximal order in $G$. There is a subgroup $H \subset G$ such that $G \cong H \times\langle g\rangle$.
Proof. Let $n$ be the order of $g$. The subgroup $\langle g\rangle$ of $G$ is cyclic of order $n$. In $S^{1}$ there is a cyclic subgroup of order $n$, namely $\mu_{n}$. Since cyclic groups of the same order are
isomorphic, there is an isomorphism $\langle g\rangle \rightarrow \mu_{n}$, so $g$ is mapped to a root of unity of order $n$. This isomorphism can be viewed as a character of $\langle g\rangle$. Extend this to a character of $G$ (Theorem 3.3), so we have a character $\chi: G \rightarrow S^{1}$ such that $\chi(g)$ has order $n$. The image $\chi(G)$ contains $\mu_{n}$, and it turns out to be no larger.

Claim: $\chi(G)=\mu_{n}$.
Since $\chi(G)$ is a finite subgroup of $S^{1}$, it is cyclic (all finite subgroups of $S^{1}$ are cyclic). Therefore $\chi(G)=\langle\chi(\gamma)\rangle$ for some $\gamma \in G$. Since $\chi(G)$ contains $\mu_{n}, \chi(G)=\mu_{n n^{\prime}}$ where $n^{\prime} \geq 1$. Thus $\chi(\gamma)$ has order $n n^{\prime}$. Let $\gamma$ have order $d$ in $G$, so $\gamma^{d}=1$ in $G$ and thus $\chi(\gamma)^{d}=1$ in $S^{1}$. That implies $n n^{\prime} \mid d$, so $n n^{\prime} \leq d$. Since $n$ is the maximal order of the elements in $G, d \leq n$. The relations $n n^{\prime} \leq d$ and $d \leq n$ imply $n^{\prime}=1$, so $\chi(G)=\mu_{n}$. This proves the claim.

Set $H=\operatorname{ker} \chi$. Then $H \cap\langle g\rangle=\{1\}$ since $\chi$ is one-to-one on $\langle g\rangle$ by construction. For each $x \in G, \chi(x) \in \chi(G)=\mu_{n}=\chi(\langle g\rangle)$, so $\chi(x)=\chi\left(g^{j}\right)$ for some $j$. Therefore $h:=x g^{-j}$ is in $H$ and $x=h g^{j}$. This proves that the multiplication map $H \times\langle g\rangle \rightarrow G$ where $\left(h, g^{j}\right) \mapsto h g^{j}$ is surjective. It is a homomorphism and its kernel is trivial, so $G \cong H \times\langle g\rangle$.

Theorem 5.2. Every finite abelian group $G$ is isomorphic to a product of cyclic groups:

$$
G \cong \mathbf{Z} /\left(n_{1}\right) \times \mathbf{Z} /\left(n_{2}\right) \times \cdots \times \mathbf{Z} /\left(n_{k}\right)
$$

Proof. Induct on $|G|$. The result is clear when $|G|=1$. When $|G|>1$, let $n$ be the maximal order of the elements of $G$, so $G \cong H \times \mathbf{Z} /(n)$ by Theorem 5.1. Since $|H|<|G|$, by induction $H$ is isomorphic to a direct product of cyclic groups, so $G$ is also isomorphic to a direct product of cyclic groups.

Theorem 5.2 can be refined: $G$ is a direct product of cyclic groups with the extra feature that $n_{1}\left|n_{2}\right| \cdots \mid n_{k}$. To prove this, use the fact that the order of each element of a finite abelian group $G$ divides the maximal order of the elements of $G$.

Exercises.

1. What is the structure (as a direct product of cyclic groups) of the finite abelian groups whose nontrivial characters all have order 2 ?
2. Mimic the proof of Theorem 5.1 to decompose $(\mathbf{Z} /(20))^{\times}$(of size 8 ) and $(\mathbf{Z} /(45))^{\times}$ (of size 24) into a direct product of cyclic groups.
3. Show by an explicit counterexample that the following is false: if two subgroups $H$ and $K$ of a finite abelian group $G$ are isomorphic then there is an automorphism of $G$ that restricts to an isomorphism from $H$ to $K$.
4. For a finite abelian group $G$, show the maximum order of the elements of $G$ and the number $|G|$ have the same prime factors. (Hint: If $g$ has order $n$ and there is an element $h$ of prime order $p$ where $p \nmid n$, what is the order of $g h$ ?)

This is false in general for nonabelian $G$, as shown in the table below where $g(n)$ (called Landau's function) is the maximal order of the elements of $S_{n}$. For $n \geq 3$ in the table, some prime factor of $n$ ! does not divide $g(n)$.

| $n$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $g(n)$ | 1 | 2 | 3 | 4 | 6 | 6 | 12 | 15 | 20 | 30 | 30 | 60 | 60 | 84 | 105 |

Table 4. Maximal order of elements of $S_{n}$
5. Let $G$ be a finite abelian group and $F$ be a field containing a full set of $|G|$ th roots of unity. (So $x^{|G|}=1$ has $|G|$ solutions in $F$.) Define characters of $G$ to be group homomorphisms $\chi: G \rightarrow F^{\times}$and write the set of all such characters as $\widehat{G}$.
a) Construct a character table for $\mathbf{Z} /(4)$ and $(\mathbf{Z} /(2))^{2}$ when $F$ is the field $\mathbf{Z} /(5)$.
b) Prove every lemma, theorem, and corollary from Section 3 for the new meaning of $\widehat{G}$. There is no longer complex conjugation on character values, but the inverse of $\chi$ is still the function $g \mapsto \chi\left(g^{-1}\right)=\chi(g)^{-1}$. (Hint: For each $d$ dividing $|G|, x^{d}=1$ has $d$ distinct solutions in $F^{\times}$, which form a cyclic group.)
c) Prove Theorem 4.1 and Corollary 4.2 for $F$-valued characters of $G$.
d) Set $L(G, F)$ to be the functions $G \rightarrow F$. This is an $F$-vector space in the same way that $L(G)$ is a complex vector space. For each function $f \in L(G, F)$, define its Fourier transform $\widehat{f} \in L(\widehat{G}, F)$ by $\widehat{f}(\chi)=\sum_{g \in G} f(g) \chi\left(g^{-1}\right)$. Prove the Fourier inversion formula and Plancherel's theorem in this context. (Note: If the field $F$ has characteristic $p$ then $1 /|G|$ in the Fourier inversion formula makes sense in $F$ since $p$ doesn't divide $|G|$ - why?)
e) Check everything you have done goes through if the assumption that $x^{|G|}=1$ has a full set of solutions in $F$ is weakened to $x^{m}=1$ having a full set of solutions in $F$, where $m$ is the maximal order of the elements of $G$. For example, if $G=(\mathbf{Z} /(2))^{d}$ then $m=2$ and we can use $F=\mathbf{Z} /(3)$.

## 6. Existence of solutions to a Mordell equation mod $p$

For $k \in \mathbf{Z}$, an equation of the form $y^{2}=x^{3}+k$ is called a Mordell equation. When $k \neq 0$, it is a hard theorem that such an equation has only finitely many integral solutions $(x, y)$, which could include having no integral solutions. ${ }^{2}$ For example, the integral solutions of $y^{2}=x^{3}-4$ are $(2, \pm 2)$ and $(5, \pm 11)$, and the equation $y^{2}=x^{3}-5$ has no integral solutions. Using characters, we will show the congruence $y^{2} \equiv x^{3}+k \bmod p$ modulo a prime $p$ always has a solution.

For a character $\chi$ on $(\mathbf{Z} /(p))^{\times}$, extend $\chi$ to $\mathbf{Z} /(p)$ by setting $\chi(0)=0$. Then $\chi(a b)=$ $\chi(a) \chi(b)$ for all $a, b \in \mathbf{Z} /(p)$.

Lemma 6.1. If $p$ is prime and $d \mid(p-1)$, there is a character $\chi$ of $(\mathbf{Z} /(p))^{\times}$with order $d$, and for each $a \in \mathbf{Z} / p \mathbf{Z}$,

$$
\left|\left\{x \in \mathbf{Z} /(p): x^{d} \equiv a \bmod p\right\}\right|=1+\chi(a)+\chi(a)^{2}+\cdots+\chi(a)^{d-1}
$$

Proof. The group $(\mathbf{Z} /(p))^{\times}$is cyclic of order $p-1,{ }^{3}$ so $\left|\left\{x \in \mathbf{Z} /(p): x^{d} \equiv 1 \bmod p\right\}\right|=d$ since $d \mid(p-1)$. Thus

$$
\left|\left\{x \in \mathbf{Z} /(p): x^{d} \equiv a \bmod p\right\}\right|= \begin{cases}d, & \text { if } a \not \equiv 0 \bmod p \text { and } a \text { is a } d \text { th power } \bmod p  \tag{6.1}\\ 1, & \text { if } a \equiv 0 \bmod p, \\ 0, & \text { if } a \text { is not a } d \text { th power } \bmod p\end{cases}
$$

The character group of $(\mathbf{Z} /(p))^{\times}$is cyclic of order $p-1$ by Theorem 3.10, so $(\mathbf{Z} /(p))^{\times}$ has a character of order $d$. Call such a character $\chi$. For each $a \in \mathbf{Z} /(p)$, we'll show that $1+\chi(a)+\chi(a)^{2}+\cdots+\chi(a)^{d-1}$ has the same values as in (6.1).

[^1]- If $a$ is a nonzero $d$ th power $\bmod p$, say $a \equiv b^{d} \bmod p$, then $\chi(a)=\chi\left(b^{d}\right)=\chi(b)^{d}=1$ since $\chi^{d}$ is identically 1 on $(\mathbf{Z} /(p))^{\times}$, so $1+\chi(a)+\chi(a)^{2}+\cdots+\chi(a)^{d-1}=d$.
- If $a \equiv 0 \bmod p$ then $\chi(a)=0$, so $1+\chi(a)+\chi(a)^{2}+\cdots+\chi(a)^{d-1}=1$.
- Lastly, if $a$ is in $(\mathbf{Z} /(p))^{\times}$and is not a $d$ th power, we'll show $\chi(a) \neq 1$, so by summing a finite geometric series,

$$
1+\chi(a)+\chi(a)^{2}+\cdots+\chi(a)^{d-1}=\frac{\chi(a)^{d}-1}{\chi(a)-1}=\frac{1-1}{\chi(a)-1}=0,
$$

which would complete the proof.
Let $g$ be a generator of $(\mathbf{Z} /(p))^{\times}$and write $a=g^{k}$ for $k \in \mathbf{Z}$.
Step 1: $\chi(g)$ has order $d$. Since $\chi$ has order $d, \chi(g)^{d}=1$, so $\chi(g)$ has order dividing $d$. Since $\chi\left((\mathbf{Z} /(p))^{\times}\right)=\langle\chi(g)\rangle$, if $\chi(g)$ has order less than $d$ then $\chi$ as a character has order less than $d$, which $\chi$ doesn't. Thus $\chi(g)$ has order $d$.

Step 2: $\chi(a) \neq 1$. If $\chi(a)=1$ then $\chi(g)^{k}=1$, so $d \mid k$ by Step 1 . Then $a=g^{k}$ is

Theorem 6.2. For each prime $p$ and $k \in \mathbf{Z}$, the congruence $y^{2} \equiv x^{3}+k \bmod p$ has at least two solutions $(x, y)$ in $\mathbf{Z} /(p)$.
Proof. We'll consider separately the cases $3 \nmid(p-1)$ and $3 \mid(p-1)$.
Case 1: $3 \nmid(p-1)$.
Since $(3, p-1)=1$, cubing is a bijection $\mathbf{Z} /(p) \rightarrow \mathbf{Z} /(p)$ (on $(\mathbf{Z} /(p))^{\times}$it is injective and thus surjective since the group is finite), so for each $y \in \mathbf{Z} /(p)$ there is a unique $x \in \mathbf{Z} /(p)$ such that $y^{2}-k \equiv x^{3} \bmod p$. Thus the number of solutions of $y^{2} \equiv x^{3}+k \bmod p$ is $p$, and $p \geq 2$.

Case 2: $3 \mid(p-1)$.
If $k \equiv 0 \bmod p$, then the congruence is $y^{2} \equiv x^{3} \bmod p$, which has the $p$ solutions $\left(a^{2}, a^{3}\right)$ for $a \in \mathbf{Z} /(p)$ (and in fact no further solutions $\bmod p)$. So now we can assume $k \not \equiv 0 \bmod p$.

Since $3 \mid(p-1)$, there is a character $\chi$ on $(\mathbf{Z} /(p))^{\times}$with order 3 , and the inverse $\chi^{2}$ of $\chi$ is the complex conjugate $\bar{\chi}$. Since $p$ is odd, there is a quadratic character $\psi$ on $(\mathbf{Z} /(p))^{\times}$ (it's the Legendre symbol). To count solutions to $y^{2} \equiv x^{3}+k \bmod p$ we will count solutions $(a, b)$ to the simpler equation $b \equiv a+k \bmod p$ and then count how often $a$ is a cube $\bmod p$ and $b$ is a square $\bmod p$.

By Lemma 6.1, the number of ways $a$ is a cube $\bmod p$ is $1+\chi(a)+\chi(a)^{2}=1+\chi(a)+\bar{\chi}(a)$, and the number of ways $b$ is a square $\bmod p$ is $1+\psi(b)$. Let $N_{p}(k)$ be the number of $\bmod$ $p$ solutions to $y^{2} \equiv x^{3}+k \bmod p$, so

$$
N_{p}(k)=\sum_{(a, b)}(1+\chi(a)+\bar{\chi}(a))(1+\psi(b)),
$$

where we sum over all $(a, b) \bmod p$ for which $b \equiv a+k \bmod p$ (either $a$ or $b$ determines the other $\bmod p)$. Expanding out the product, we get a sum of 6 terms over all the pairs ( $a, b$ ) where $b \equiv a+k \bmod p$ :

$$
N_{p}(k)=\sum_{(a, b)}(1+\chi(a)+\bar{\chi}(a)+\psi(b)+\chi(a) \psi(b)+\bar{\chi}(a) \psi(b)) .
$$

Split this up into 6 sums. The first sum is $p$ since the number of possible $(a, b)$ is $p$ (both $a$ and $b$ determine each other $\bmod p$ and each is free to take on any value). The second, third, and fourth sums are 0 since the sum of a nontrivial multiplicative character over $\mathbf{Z} /(p)$ is 0 (a term where $a=0$ or $b=0$ can be dropped since $\chi(0)=0$ and $\psi(0)=0$ ).

We're left with the sums of $\chi(a) \psi(b)$ and $\bar{\chi}(a) \psi(b)$, and at this point let's write $b$ directly in terms of $a($ and $k)$ so we can write the sums as running over all $a \bmod p$ :

$$
N_{p}(k)=p+\sum_{a} \chi(a) \psi(a+k)+\sum_{a} \bar{\chi}(a) \psi(a+k) .
$$

Since $k \not \equiv 0 \bmod p$, we can make the change of variables $a \mapsto k a$ in both sums and pull out the character values at $k$ :

$$
N_{p}(k)=p+\chi(k) \psi(k) \sum_{a} \chi(a) \psi(a+1)+\bar{\chi}(k) \psi(k) \sum_{a} \bar{\chi}(a) \psi(a+1) .
$$

Replace $a \bmod p$ with $-a \bmod p$ in the sums:

$$
N_{p}(k)=p+\chi(-k) \psi(k) \sum_{a} \chi(a) \psi(1-a)+\bar{\chi}(-k) \psi(k) \sum_{a} \bar{\chi}(a) \psi(1-a) .
$$

Set $S=\sum_{a} \chi(a) \psi(1-a)$, so $\bar{S}=\sum_{a} \bar{\chi}(a) \psi(1-a)$ since $\psi$-values are $\pm 1$, and

$$
N_{p}(k)=p+\chi(-k) \psi(k) S+\bar{\chi}(-k) \psi(k) \bar{S}=p+2 \operatorname{Re}(\chi(-k) \psi(k) S) .
$$

For each complex number $z,|\operatorname{Re}(z)| \leq \sqrt{|z|}$, so $\left|N_{p}(k)-p\right| \leq 2 \sqrt{|S|}$. Since $\chi$ and $\psi$ are nontrivial multiplicative characters $\bmod p$ and $\chi \psi$ is nontrivial, $|S|=\sqrt{p}{ }^{4}$ Thus $\left|N_{p}(k)-p\right| \leq 2 \sqrt{p}$, so $N_{p}(k) \geq p-2 \sqrt{p}$. The function $f(t)=t-2 \sqrt{t}$ is increasing for $t>1$, the least prime $p \equiv 1 \bmod 3$ is 7 , and $7-2 \sqrt{7} \approx 1.7$, so $N_{p}(k) \geq 2$ when $3 \mid(p-1)$.

Exercises.

1. For prime $p$ and $n \in \mathbf{Z}^{+}$, set $d=(n, p-1)$. For $r \in \mathbf{Z}$, let $\varphi_{r}:(\mathbf{Z} /(p))^{\times} \rightarrow(\mathbf{Z} /(p))^{\times}$ by $\varphi_{r}(x)=x^{r}$.
a) Show $\varphi_{n}$ and $\varphi_{d}$ have the same image and kernel. (Hint: $d$ is a Z-linear combination of $n$ and $p-1$.)
b) For nonzero $a$ in $\mathbf{Z} /(p)$, use (a) to show the equations $x^{n}=a$ and $x^{d}=a$ have the same number of solutions in $\mathbf{Z} /(p)$.
c) Find all solutions of $x^{4}=3$ and of $x^{2}=3$ in $\mathbf{Z} /(11)$. (There are two solutions in each case.)
d) For nonzero $a$ in $\mathbf{Z} /(p)$, show $x^{n}+y^{n}=a$ and $x^{d}+y^{d}=a$ have the same number of solutions in $\mathbf{Z} /(p)$.
2. Let $p$ be prime, $a$ be nonzero in $\mathbf{Z} /(p)$, and $d$ be a positive factor of $p-1$. We want to estimate the number of solutions of $x^{d}+y^{d}=a$ in $\mathbf{Z} /(p)$.
a) For a polynomial $f(x)$ with coefficients in $\mathbf{Z} /(p)$, let $N(f(x)=a)$ be the number of solutions of $f(x)=a$ in $\mathbf{Z} /(p)$. By Lemma 6.1, $(\mathbf{Z} /(p))^{\times}$has a character $\chi$ of order $d$ and we set $\chi(0)=0$. Show

$$
\begin{aligned}
N\left(x^{d}+y^{d}=a\right) & =\sum_{\substack{b, c \in \mathbf{Z} /(p) \\
b+c=a}} N\left(x^{d}=b\right) N\left(y^{d}=c\right) \\
& =\sum_{b \in \mathbf{Z} /(p)}\left(1+\sum_{i=1}^{d-1} \chi(b)^{i}\right)\left(1+\sum_{j=1}^{d-1} \chi(a-b)^{j}\right) .
\end{aligned}
$$

[^2]b) Expand the product in (a) and rearrange terms to show
\[

$$
\begin{aligned}
N\left(x^{d}+y^{d}=a\right) & =p+\sum_{1 \leq i, j \leq d-1} \sum_{b \in \mathbf{Z} /(p)} \chi(b)^{i} \chi(a-b)^{j} \\
& =p+\sum_{1 \leq i, j \leq d-1} \chi(a)^{i+j} \sum_{b \in \mathbf{Z} /(p)} \chi(b)^{i} \chi(1-b)^{j} .
\end{aligned}
$$
\]

c) For characters $\psi$ and $\psi^{\prime}$ on $(\mathbf{Z} /(p))^{\times}$, set $J\left(\psi, \psi^{\prime}\right)=\sum_{b \in \mathbf{Z} /(p)} \psi(b) \psi^{\prime}(1-b)$ (it is called a Jacobi sum), so by (b),

$$
N\left(x^{d}+y^{d}=a\right)=p+\sum_{1 \leq i, j \leq d-1} \chi(a)^{i+j} J\left(\chi^{i}, \chi^{j}\right)
$$

For a nontrivial character $\psi$ on $(\mathbf{Z} /(p))^{\times}, J(\psi, \bar{\psi})=-\psi(-1) .{ }^{5}$ Use that to show

$$
N\left(x^{d}+y^{d}=a\right)=p+1-N\left(x^{d}=-1\right)+\sum_{\substack{1 \leq i, j \leq d-1 \\ i+j \neq d}} \chi(a)^{i+j} \sum_{b \in \mathbf{Z} /(p)} \chi(b)^{i} \chi(1-b)^{j}
$$

d) When $\psi, \psi^{\prime}$, and $\psi \psi^{\prime}$ are all nontrivial, $\left|J\left(\psi, \psi^{\prime}\right)\right|=\sqrt{p} .{ }^{6}$ Use that and (c) to show

$$
\left|N\left(x^{d}+y^{d}=a\right)-(p+1)\right| \leq d+(d-1)(d-2) \sqrt{p}
$$

e) Use part (d) and Exercise $6.1(\mathrm{~d})$ to show for $n \in \mathbf{Z}^{+}$and sufficiently large $p$ (depending only on $n$ ) that each equation $x^{n}+y^{n}=a$ for $a \in(\mathbf{Z} /(p))^{\times}$has a solution in $\mathbf{Z} /(p)$ where $x$ and $y$ are both nonzero.
