## SIMULTANEOUSLY ALIGNED BASES

KEITH CONRAD

Let $R$ be a PID, $n$ be a positive integer, and $M$ be a finite free $R$-module of rank $n$. By the structure theorem for modules over a PID, for any submodule $M^{\prime}$ of $M$ also having rank $n$ (to be called a full submodule of $M$ ) we can find a basis $e_{1}, \ldots, e_{n}$ of $M$ and nonzero $a_{1}, \ldots, a_{n}$ in $R$ such that $a_{1} e_{1}, \ldots, a_{n} e_{n}$ is a basis of $M^{\prime}$. We call such a pair of bases of $M$ and $M^{\prime}$ aligned.

Pick two full submodules of $M$, say $M^{\prime}$ and $M^{\prime \prime}$. If there is a basis $e_{1}, \ldots, e_{n}$ of $M$ and two sets of nonzero $a_{1}^{\prime}, \ldots, a_{n}^{\prime}$ and $a_{1}^{\prime \prime}, \ldots, a_{n}^{\prime \prime}$ in $R$ such that

$$
M=\bigoplus_{i=1}^{n} R e_{i}, \quad M^{\prime}=\bigoplus_{i=1}^{n} R a_{i}^{\prime} e_{i}, \quad M^{\prime \prime}=\bigoplus_{i=1}^{n} R a_{i}^{\prime \prime} e_{i}
$$

then we'll say $M^{\prime}$ and $M^{\prime \prime}$ admit simultaneously aligned bases. Do such bases always exist? Of course if $R$ is a field then they do because the only full submodule of $M$ is $M$, so the situation is trivial.

The following example shows simultaneously aligned bases need not exist in $R^{2}$ if $R$ is not a field.

Example 1. Let $R$ be a PID that is not a field, so $R$ contains prime elements. Let $\pi$ be prime in $R$. Inside $R^{2}$ set

$$
\begin{equation*}
M^{\prime}=R\binom{1}{0}+R\binom{0}{\pi^{2}}=\left\{\binom{x}{y}: y \equiv 0 \bmod \pi^{2}\right\} \tag{1}
\end{equation*}
$$

and

$$
\begin{equation*}
M^{\prime \prime}=R\binom{\pi}{0}+R\binom{1}{\pi}=\left\{\binom{x}{y}: y \equiv 0 \bmod \pi, \pi x \equiv y \bmod \pi^{2}\right\} \tag{2}
\end{equation*}
$$

First we determine an aligned basis for $M^{\prime}$ and for $M^{\prime \prime}$ as submodules of $R^{2}$. The first one is easy: $M^{\prime}=R\binom{1}{0}+R \pi^{2}\binom{0}{1}$, so we can use $\left\{\binom{1}{0},\binom{0}{1}\right\}$ as a basis of $R^{2}$ and $\left\{\binom{1}{0}, \pi^{2}\binom{0}{1}\right\}$ as a basis of $M^{\prime}$. For $M^{\prime \prime}$, we rewrite it as

$$
M^{\prime \prime}=R\binom{0}{\pi^{2}}+R\binom{1}{\pi}=R \pi^{2}\binom{0}{1}+R\binom{1}{\pi},
$$

so we can use $\left\{\binom{0}{1},\binom{1}{\pi}\right\}$ as a basis of $R^{2}$ and $\left\{\pi^{2}\binom{0}{1},\binom{1}{\pi}\right\}$ as a basis of $M^{\prime \prime}$. Using these aligned bases we see that $R^{2} / M^{\prime}$ and $R^{2} / M^{\prime \prime}$ are both isomorphic to $R /\left(\pi^{2}\right)$.

Suppose there is some basis $\left\{e_{1}, e_{2}\right\}$ of $R^{2}$ and nonzero $a_{1}, a_{2}, b_{1}, b_{2}$ in $R$ such that $\left\{a_{1} e_{1}, a_{2} e_{2}\right\}$ is a basis of $M^{\prime}$ and $\left\{b_{1} e_{1}, b_{2} e_{2}\right\}$ is a basis of $M^{\prime \prime}$. We are going to get a contradiction. Since $R^{2} / M^{\prime} \cong R /\left(a_{1}\right) \times R /\left(a_{2}\right)$ and $R^{2} / M^{\prime \prime} \cong R /\left(b_{1}\right) \times R /\left(b_{2}\right)$, from the known structure of $R^{2} / M^{\prime}$ and $R^{2} / M^{\prime \prime}$ we have

$$
\begin{equation*}
\left(a_{1} a_{2}\right)=\left(\pi^{2}\right), \quad\left(b_{1} b_{2}\right)=\left(\pi^{2}\right) \tag{3}
\end{equation*}
$$

Write $e_{1}=\binom{x_{1}}{y_{1}}$ and $e_{2}=\binom{x_{2}}{y_{2}}$, so being a basis of $R^{2}$ is equivalent to

$$
\begin{equation*}
x_{1} y_{2}-x_{2} y_{1} \in R^{\times} . \tag{4}
\end{equation*}
$$

Granting (3), to have $\left\{a_{1} e_{1}, a_{2} e_{2}\right\}$ be a basis of $M^{\prime}$ and $\left\{b_{1} e_{1}, b_{2} e_{2}\right\}$ be a basis of $M^{\prime \prime}$ is equivalent to having $a_{1} e_{1}$ and $a_{2} e_{2}$ lying in $M^{\prime}$ and $b_{1} e_{1}$ and $b_{2} e_{2}$ lying in $M^{\prime \prime}$.

Having $a_{1} e_{1}=\binom{a_{1} x_{1}}{a_{1} y_{1}}$ and $a_{2} e_{2}=\binom{a_{2} x_{2}}{a_{2} y_{2}}$ in $M^{\prime}$ is equivalent to $a_{1} y_{1}, a_{2} y_{2} \equiv 0 \bmod \pi^{2}$. By (4), $y_{1}$ and $y_{2}$ can't both be divisible by $\pi$, so one of $a_{1}$ or $a_{2}$ is divisible by $\pi^{2}$. Therefore by (3), $\left\{\left(a_{1}\right),\left(a_{2}\right)\right\}=\left\{(1),\left(\pi^{2}\right)\right\}$. So far the roles of $e_{1}$ and $e_{2}$ have been symmetric, so without loss of generality we can take

$$
\left(a_{1}\right)=(1), \quad\left(a_{2}\right)=\left(\pi^{2}\right)
$$

Therefore $y_{1} \equiv 0 \bmod \pi^{2}$, so $y_{2} \not \equiv 0 \bmod \pi$ (because $y_{1}$ and $y_{2}$ are relatively prime).
Having $b_{1} e_{1}=\binom{b_{1} x_{1}}{b_{1} y_{1}}$ and $b_{2} e_{2}=\binom{b_{2} x_{2}}{b_{2} y_{2}}$ in $M^{\prime \prime}$ implies $b_{1} y_{1}, b_{2} y_{2} \equiv 0 \bmod \pi$, so $b_{2} \equiv$ $0 \bmod \pi$. It also implies, by (2), that $\pi b_{1} x_{1} \equiv b_{1} y_{1} \bmod \pi^{2}$ and $\pi b_{2} x_{2} \equiv b_{2} y_{2} \bmod \pi^{2}$. Since $y_{1}$ is a multiple of $\pi^{2}$ and $b_{2}$ is a multiple of $\pi$, these congruences $\bmod \pi^{2}$ become $\pi b_{1} x_{1} \equiv 0 \bmod \pi^{2}$ and $0 \equiv b_{2} y_{2} \bmod \pi^{2}$. Since $y_{2}$ is not a multiple of $\pi, b_{2} \equiv 0 \bmod \pi^{2}$, so from (3) we have $\left(b_{1}\right)=(1)$ and $\left(b_{2}\right)=\left(\pi^{2}\right)$. Therefore $\pi b_{1} x_{1} \equiv 0 \bmod \pi^{2} \Rightarrow x_{1} \equiv 0 \bmod \pi$. But $x_{1}$ and $y_{1}$ can't both be multiples of $\pi$ since they are relatively prime, so we have a contradiction.

We now seek a criterion on pairs of full submodules that determines when they have simultaneously aligned bases. When $M$ is a finite free $R$-module and $M^{\prime}$ is a full submodule with aligned bases $\left\{e_{1}, \ldots, e_{n}\right\}$ for $M$ and $\left\{a_{1} e_{1}, \ldots, a_{n} e_{n}\right\}$ for $M^{\prime}$, the linear operator $A: M \rightarrow M$ where $A\left(e_{i}\right)=a_{i} e_{i}$ has image $M^{\prime}$ and $\operatorname{det} A=a_{1} \cdots a_{n} \neq 0$. Conversely, if $A: M \rightarrow M$ is a linear operator with nonzero determinant, then $A(M)$ is a full submodule of $M$ with $(\operatorname{det} A)=\left(c_{1} \cdots c_{k}\right)$ as ideals, where $M / A(M)$ has the cyclic decomposition $R /\left(c_{1}\right) \times \cdots \times R /\left(c_{k}\right)$. Therefore the full submodules of $M$ are the same thing as images of linear operators $A: M \rightarrow M$ with nonzero determinant, and $\operatorname{det} A$ is determined up to unit multiple by the structure of $M / A(M)$ as an $R$-module. Writing a full submodule $M^{\prime}$ of $M$ as $A(M)$ for some linear operator $A$ on $M$, how much does $M^{\prime}$ determine $A$ ?

Lemma 2. If $A_{1}$ and $A_{2}$ are two linear operators on $M$ with nonzero determinant, then $A_{1}(M)=A_{2}(M)$ if and only if $A_{1}=A_{2} U$ for some $U \in \operatorname{GL}(M)$.

Proof. Let $e_{1}, \ldots, e_{n}$ be a basis of $M$. If $A_{1}(M)=A_{2}(M)$ then $A_{1}\left(e_{i}\right)=A_{2}\left(f_{i}\right)$ for some $f_{i} \in M$. Let $U: M \rightarrow M$ be the linear map satisfying $U\left(e_{i}\right)=f_{i}$ for all $i$. Then $A_{1}\left(e_{i}\right)=$ $A_{2}\left(U\left(e_{i}\right)\right)=A_{2} U\left(e_{i}\right)$, so by linearity $A_{1}(m)=A_{2} U(m)$ for all $m \in M$, and thus $A_{1}=A_{2} U$. From $A_{1}(M)=A_{2}(M)$ we get $M / A_{1}(M)=M / A_{2}(M)$, so $\operatorname{det} A_{1}$ and $\operatorname{det} A_{2}$ are equal up to unit multiple. Then the condition $\operatorname{det} A_{1}=\left(\operatorname{det} A_{2}\right)(\operatorname{det} U)$ implies $\operatorname{det} U \in R^{\times}$, so $U \in \operatorname{GL}(M)$.

Conversely, if $A_{1}=A_{2} U$ with $U \in \operatorname{GL}(M)$ then $A_{1}(M)=A_{2}(U(M))=A_{2}(M)$.
By this lemma, if we write a full submodule of $M$ as $A(M)$ for some $A \in \operatorname{End}(M)$, then $A$ is determined by $A(M)$ up to right multiplication by an element of GL( $M$ ).

Pick two full submodules of $M$, say $A(M)$ and $B(M)$, with simultaneously aligned bases: there is a basis $e_{1}, \ldots, e_{n}$ of $M$ and two sets of $n$ nonzero $a_{1}, \ldots, a_{n}$ and $b_{1}, \ldots, b_{n}$ in $R$ such that

$$
M=\bigoplus_{i=1}^{n} R e_{i}, \quad A(M)=\bigoplus_{i=1}^{n} R a_{i} e_{i}, \quad B(M)=\bigoplus_{i=1}^{n} R b_{i} e_{i}
$$

Let $D: M \rightarrow M$ and $D^{\prime}: M \rightarrow M$ be the linear maps defined by $D\left(e_{i}\right)=a_{i} e_{i}$ and $D^{\prime}\left(e_{i}\right)=$ $b_{i} e_{i}$. Written as matrices with respect to the basis $e_{1}, \ldots, e_{n}$, both $D$ and $D^{\prime}$ become diagonal matrices, so $D$ and $D^{\prime}$ are diagonalizable operators on $M$. Easily $A(M)=D(M)$ and $B(M)=D^{\prime}(M)$, so $D=A U$ and $D^{\prime}=B V$ for some $U$ and $V$ in GL $(M)$. Obviously $D$ and $D^{\prime}$ commute, so $A U$ and $B V$ commute. We now show the converse is true too.

Theorem 3. Choose $A$ and $B$ in $\operatorname{End}(M)$ with $\operatorname{det} A \neq 0$ and $\operatorname{det} B \neq 0$. Suppose there are $U$ and $V$ in $\mathrm{GL}(M)$ such that $A U$ and $B V$ commute and are diagonalizable. Then the submodules $A(M)$ and $B(M)$ of $M$ have simultaneously aligned bases.
Proof. Set $A^{\prime}=A U$ and $B^{\prime}=B V$, so $A^{\prime}(M)=A(M)$ and $B^{\prime}(M)=B(M)$. Since $A^{\prime}$ is diagonalizable, there is a basis $e_{1}, \ldots, e_{n}$ of $M$ and nonzero $a_{1}, \ldots, a_{n}$ in $R$ such that $A^{\prime}\left(e_{i}\right)=a_{i} e_{i}$ for all $i$. Then

$$
M=\bigoplus_{i=1}^{n} R e_{i}, \quad A^{\prime}(M)=\bigoplus_{i=1}^{n} R A^{\prime}\left(e_{i}\right)=\bigoplus_{i=1}^{n} R a_{i} e_{i} .
$$

Let $\lambda_{1}, \ldots, \lambda_{k}$ be the distinct values among $a_{1}, \ldots, a_{n}$ and set $M_{j}=\left\{v \in M: A^{\prime}(v)=\lambda_{j} v\right\}$ (this is the $\lambda_{j}$-eigenspace of $A^{\prime}$ ). Each $e_{i}$ is in some $M_{j}$, so $M=M_{1}+M_{2}+\cdots+M_{k}$. Elements from different $M_{j}$ 's are linearly independent (same as proof in vector spaces that eigenvectors for different eigenvalues of a linear operator are linearly independent). Therefore

$$
M=M_{1} \oplus \cdots \oplus M_{k} .
$$

For $v \in M_{j}, A^{\prime}\left(B^{\prime} v\right)=B^{\prime}\left(A^{\prime} v\right)=B^{\prime}\left(\lambda_{j} v\right)=\lambda_{j}\left(B^{\prime} v\right)$, so $B^{\prime}\left(M_{j}\right) \subset M_{j}$ for all $j$. Let $d_{j}$ be the rank of $M_{j}$. Since $M_{j}$ is a finite free $R$-module, the structure theorem for modules over a PID says there is a basis $e_{1 j}, \ldots, e_{d_{j} j}$ of $M_{j}$ and nonzero $c_{1 j}, \ldots, c_{d_{j} j}$ in $R$ such that

$$
M_{j}=R e_{1 j} \oplus \cdots \oplus R e_{d_{j} j}, \quad B^{\prime}\left(M_{j}\right)=R c_{1 j} e_{1 j} \oplus \cdots \oplus R c_{d_{j} j} e_{d_{j} j}
$$

Then

$$
\begin{gathered}
M=\bigoplus_{j=1}^{k} M_{j}=\bigoplus_{j=1}^{k} \bigoplus_{\ell=1}^{d_{j}} R e_{\ell j}, \\
B(M)=B^{\prime}(M)=\bigoplus_{j=1}^{k} B^{\prime}\left(M_{j}\right)=\bigoplus_{j=1}^{k} \bigoplus_{\ell=1}^{d_{j}} R c_{\ell j} e_{\ell j},
\end{gathered}
$$

and

$$
A(M)=A^{\prime}(M)=\bigoplus_{j=1}^{k} A^{\prime}\left(M_{j}\right)=\bigoplus_{j=1}^{k} \lambda_{j} M_{j}=\bigoplus_{j=1}^{k} \bigoplus_{\ell=1}^{d_{j}} R \lambda_{j} e_{\ell j} .
$$

We have found simultaneously aligned bases for $A(M)$ and $B(M)$ in $M$.
Let's consider now any finite number of full submodules, not just two. The definition of simultaneously aligned bases for more than two full submodules of a finite free $R$-module is clear: a basis for the whole module that can be scaled to a basis of each of the submodules.

Example 4. If we view the ring of integers of a number field as a Z-module, any finite set of nonzero ideals in it has simultaneously aligned $\mathbf{Z}$-bases. This is proved in [1], where Example 1 also appears for the case $R=\mathbf{Z}$ and $\pi=3$.

Corollary 5. For $r \geq 2$ and $A_{1}, \ldots, A_{r}$ in $\operatorname{End}(M)$ with nonzero determinants, the submodules $A_{1}(M), \ldots, A_{r}(M)$ of $M$ have simultaneously aligned bases if and only if there are $U_{1}, \ldots, U_{r}$ in $\mathrm{GL}(M)$ such that $A_{1} U_{1}, \ldots, A_{r} U_{r}$ are diagonalizable and pairwise commuting.

In particular, if $A_{1}, \ldots, A_{r}$ are diagonalizable and pairwise commuting in $\operatorname{End}(M)$ with nonzero determinants then the submodules $A_{1}(M), \ldots, A_{r}(M)$ of $M$ have simultaneously aligned bases.
Proof. If there are simultaneously aligned bases for $A_{1}(M), \ldots, A_{r}(M)$, then the same argument as before leads to $U_{1}, \ldots, U_{r}$ in $\mathrm{GL}(M)$ such that $A_{1} U_{1}, \ldots, A_{r} U_{r}$ are diagonalizable and pairwise commuting.

Conversely, suppose there are $U_{1}, \ldots, U_{r}$ in GL $(M)$ such that $A_{1} U_{1}, \ldots, A_{r} U_{r}$ are diagonalizable and pairwise commuting operators on $M$. Set $A_{1}^{\prime}=A_{1} U_{1}, \ldots, A_{r}^{\prime}=A_{r} U_{r}$. We want to show the submodules $A_{1}(M), \ldots A_{r}(M)$ have simultaneously aligned bases in $M$. Since $A_{1}^{\prime}(M)=A_{1}(M), \ldots, A_{r}^{\prime}(M)=A_{r}(M)$, we can replace $A_{1}, \ldots, A_{r}$ with $A_{1}^{\prime}, \ldots, A_{r}^{\prime}$ : to show $A_{1}^{\prime}(M), \ldots, A_{r}^{\prime}(M)$ have simultaneously aligned bases when $A_{1}^{\prime}, \ldots, A_{r}^{\prime}$ are diagonalizable and pairwise commuting, we will proceed by the same inductive argument that is used to show a set of commuting diagonalizable operators on a finite-dimensional vector space are simultaneously diagonalizable.

Since $A_{1}^{\prime}$ is diagonalizable, there is a basis $e_{1}, \ldots, e_{n}$ of $M$ and nonzero $a_{1}, \ldots, a_{n}$ in $R$ such that $A_{1}^{\prime}\left(e_{i}\right)=a_{i} e_{i}$ for all $i$, so

$$
M=\bigoplus_{i=1}^{n} R e_{i}, \quad A_{1}^{\prime}(M)=\bigoplus_{i=1}^{n} R A_{1}^{\prime}\left(e_{i}\right)=\bigoplus_{i=1}^{n} R a_{i} e_{i} .
$$

Let $\lambda_{1}, \ldots, \lambda_{k}$ be the distinct values among $a_{1}, \ldots, a_{n}$. Then as before,

$$
M=M_{1} \oplus \cdots \oplus M_{k},
$$

where $M_{j}=\left\{v \in M: A_{1}^{\prime}(v)=\lambda_{j} v\right\}$ (and $M_{j} \neq\{0\}$ ). As before, each $M_{j}$ is preserved by $A_{2}^{\prime}, \ldots, A_{r}^{\prime}$ and the restrictions of these operators ${ }^{1}$ to $M_{j}$ are pairwise commuting with nonzero determinant. Once we show the restrictions of $A_{2}^{\prime}, \ldots, A_{r}^{\prime}$ to $M_{j}$ are each diagonalizable, then by induction on the number of operators there are simultaneously aligned bases for $A_{2}^{\prime}\left(M_{j}\right), \ldots, A_{r}^{\prime}\left(M_{j}\right)$ as submodules of $M_{j}$ (that is, each $M_{j}$ has a basis that can be scaled termwise to provide a basis of those submodules). All elements of $M_{j}$ are eigenvectors for $A_{1}^{\prime}$, so by stringing together bases of $M_{1}, \ldots, M_{k}$ to give a basis of $M$ we have a simultaneously aligned basis for $A_{1}^{\prime}(M), \ldots, A_{r}^{\prime}(M)$ in $M$, and then we'd be done (since $\left.A_{1}^{\prime}(M)=A_{1}(M), \ldots, A_{r}^{\prime}(M)=A_{r}(M)\right)$.
