# TENSOR PRODUCTS 

KEITH CONRAD

## 1. Introduction

Let $R$ be a commutative ring and $M$ and $N$ be $R$-modules. (We always work with rings having a multiplicative identity and modules are assumed to be unital: $1 \cdot m=m$ for all $m \in M$.) The direct sum $M \oplus N$ is an addition operation on modules. We introduce here a product operation $M \otimes_{R} N$, called the tensor product. We will start off by describing what a tensor product of modules is supposed to look like. Rigorous definitions are in Section 3.

Tensor products first arose for vector spaces, and this is the only setting where they occur in physics and engineering, so we'll describe tensor products of vector spaces first. Let $V$ and $W$ be vector spaces over a field $K$, and choose bases $\left\{e_{i}\right\}$ for $V$ and $\left\{f_{j}\right\}$ for $W$. The tensor product $V \otimes_{K} W$ is defined to be the $K$-vector space with a basis of formal symbols $e_{i} \otimes f_{j}$ (we declare these new symbols to be linearly independent by definition). Thus $V \otimes_{K} W$ is the formal sums $\sum_{i, j} c_{i j} e_{i} \otimes f_{j}$ with $c_{i j} \in K$. Elements of $V \otimes_{K} W$ are called tensors. For $v \in V$ and $w \in W$, define $v \otimes w$ to be the element of $V \otimes_{K} W$ obtained by writing $v$ and $w$ in terms of the original bases of $V$ and $W$ and then expanding out $v \otimes w$ as if $\otimes$ were a noncommutative product (allowing scalars to be pulled out).

For example, let $V=W=\mathbf{R}^{2}=\mathbf{R} e_{1}+\mathbf{R} e_{2}$, where $\left\{e_{1}, e_{2}\right\}$ is the standard basis. (We use the same basis for both copies of $\mathbf{R}^{2}$.) Then $\mathbf{R}^{2} \otimes_{\mathbf{R}} \mathbf{R}^{2}$ is a 4 -dimensional space with basis $e_{1} \otimes e_{1}, e_{1} \otimes e_{2}, e_{2} \otimes e_{1}$, and $e_{2} \otimes e_{2}$. If $v=e_{1}-e_{2}$ and $w=e_{1}+2 e_{2}$, then

$$
\begin{equation*}
v \otimes w=\left(e_{1}-e_{2}\right) \otimes\left(e_{1}+2 e_{2}\right):=e_{1} \otimes e_{1}+2 e_{1} \otimes e_{2}-e_{2} \otimes e_{1}-2 e_{2} \otimes e_{2} . \tag{1.1}
\end{equation*}
$$

Does $v \otimes w$ depend on the choice of a basis of $\mathbf{R}^{2}$ ? As a test, pick another basis, say $e_{1}^{\prime}=e_{1}+e_{2}$ and $e_{2}^{\prime}=2 e_{1}-e_{2}$. Then $v$ and $w$ can be written as $v=-\frac{1}{3} e_{1}^{\prime}+\frac{2}{3} e_{2}^{\prime}$ and $w=\frac{5}{3} e_{1}^{\prime}-\frac{1}{3} e_{2}^{\prime}$. By a formal calculation,
$v \otimes w=\left(-\frac{1}{3} e_{1}^{\prime}+\frac{2}{3} e_{2}^{\prime}\right) \otimes\left(\frac{5}{3} e_{1}^{\prime}-\frac{1}{3} e_{2}^{\prime}\right)=-\frac{5}{9} e_{1}^{\prime} \otimes e_{1}^{\prime}+\frac{1}{9} e_{1}^{\prime} \otimes e_{2}^{\prime}+\frac{10}{9} e_{2}^{\prime} \otimes e_{1}^{\prime}-\frac{2}{9} e_{2}^{\prime} \otimes e_{2}^{\prime}$,
and if you substitute into this last linear combination the definitions of $e_{1}^{\prime}$ and $e_{2}^{\prime}$ in terms of $e_{1}$ and $e_{2}$, expand everything out, and collect like terms, you'll return to the sum on the right side of (1.1). This suggests that $v \otimes w$ has a meaning in $\mathbf{R}^{2} \otimes_{\mathbf{R}} \mathbf{R}^{2}$ that is independent of the choice of a basis, although proving that might look daunting.

In the setting of modules, a tensor product can be described like the case of vector spaces, but the properties that $\otimes$ is supposed to satisfy have to be laid out in general, not just on a basis (which may not even exist): for $R$-modules $M$ and $N$, their tensor product $M \otimes_{R} N$ (read as " $M$ tensor $N$ " or " $M$ tensor $N$ over $R$ ") is an $R$-module spanned - not as a basis, but just as a spanning set ${ }^{1}$ - by all symbols $m \otimes n$, with $m \in M$ and $n \in N$, and these

[^0]symbols satisfy distributive laws:
\[

$$
\begin{equation*}
\left(m+m^{\prime}\right) \otimes n=m \otimes n+m^{\prime} \otimes n, \quad m \otimes\left(n+n^{\prime}\right)=m \otimes n+m \otimes n^{\prime} . \tag{1.2}
\end{equation*}
$$

\]

Also multiplication by $r \in R$ can be put into either side of $\otimes$ : for $m \in M$ and $n \in N$,

$$
\begin{equation*}
r(m \otimes n)=(r m) \otimes n=m \otimes(r n) . \tag{1.3}
\end{equation*}
$$

Therefore writing $r m \otimes n$ is unambiguous: it is both $r(m \otimes n)$ and $(r m) \otimes n$.
The formulas (1.2) and (1.3) in $M \otimes_{R} N$ should be contrasted with those for the direct sum $M \oplus N$, where

$$
\left(m+m^{\prime}, n\right)=(m, n)+\left(m^{\prime}, 0\right), \quad r(m, n)=(r m, r n)
$$

In $M \oplus N$, an element $(m, n)$ decomposes as $(m, 0)+(0, n)$, but $m \otimes n$ in $M \otimes_{R} N$ does not break apart. While every element of $M \oplus N$ is a pair $(m, n)$, there are usually more elements of $M \otimes_{R} N$ than the products $m \otimes n$. The general element of $M \otimes_{R} N$, which is called a tensor, is an $R$-linear combination ${ }^{2}$

$$
r_{1}\left(m_{1} \otimes n_{1}\right)+r_{2}\left(m_{2} \otimes n_{2}\right)+\cdots+r_{k}\left(m_{k} \otimes n_{k}\right),
$$

where $k \geq 1, r_{i} \in R, m_{i} \in M$, and $n_{i} \in N$. Since $r_{i}\left(m_{i} \otimes n_{i}\right)=\left(r_{i} m_{i}\right) \otimes n_{i}$, we can rename $r_{i} m_{i}$ as $m_{i}$ and write the above linear combination as a sum

$$
\begin{equation*}
m_{1} \otimes n_{1}+m_{2} \otimes n_{2}+\cdots+m_{k} \otimes n_{k} . \tag{1.4}
\end{equation*}
$$

In the direct sum $M \oplus N$, equality is easy to define: $(m, n)=\left(m^{\prime}, n^{\prime}\right)$ if and only if $m=m^{\prime}$ and $n=n^{\prime}$. When are two sums of the form (1.4) equal in $M \otimes_{R} N$ ? This is not easy to say in terms of the description of a tensor product that we have given, except in one case: $M$ and $N$ are free $R$-modules with bases $\left\{e_{i}\right\}$ and $\left\{f_{j}\right\}$. In this case, $M \otimes_{R} N$ is free with basis $\left\{e_{i} \otimes f_{j}\right\}$, so every element of $M \otimes_{R} N$ is a (finite) sum $\sum_{i, j} c_{i j} e_{i} \otimes f_{j}$ with $c_{i j} \in R$ and two such sums are equal only when coefficients of like terms are equal.

To describe equality in $M \otimes_{R} N$ when $M$ and $N$ don't have bases, we will use a universal mapping property of $M \otimes_{R} N$. The tensor product is the first concept in algebra whose properties make consistent sense only by a universal mapping property, which is: $M \otimes_{R} N$ is the universal object that turns bilinear maps on $M \times N$ into linear maps. As Jeremy Kun [13] writes, $M \otimes_{R} N$ is the "gatekeeper" of all bilinear maps out of $M \times N$.

After a discussion of bilinear (and multilinear) maps in Section 2, the definition and construction of the tensor product is presented in Section 3. Examples of tensor products are in Section 4. In Section 5 we will show how the tensor product interacts with some other constructions on modules. Section 6 describes the important operation of base extension, which is a process of using tensor products to turn an $R$-module into an $S$-module where $S$ is another ring. Finally, in Section 7 we describe the notation used for tensors in physics.

Here is a brief history of tensors and tensor products. Tensor comes from the Latin tendere, which means "to stretch." In 1822 Cauchy introduced the Cauchy stress tensor in continuum mechanics, and in 1861 Riemann created the Riemann curvature tensor in geometry, but they did not use those names. In 1884, Gibbs [7, Chap. 3] introduced tensor products of vectors in $\mathbf{R}^{3}$ with the label "indeterminate product" ${ }^{3}$ and applied it to study

[^1]strain on a body. He extended the indeterminate product to $n$ dimensions in 1886 [8]. Voigt used tensors to describe stress and strain on crystals in 1898 [25], and the term tensor first appeared with its modern physical meaning there. ${ }^{4}$ In geometry Ricci used tensors in the late 1800s and his 1901 paper [22] with Levi-Civita (in English in [15]) was crucial in Einstein's work on general relativity. Wide use of the term "tensor" in physics and math is due to Einstein; Ricci and Levi-Civita called tensors by the bland name "systems". The notation $\otimes$ is due to Murray and von Neumann in 1936 [17, Chap. II] for tensor products (they wrote "direct products") of Hilbert spaces. ${ }^{5}$ The tensor product of abelian groups $A$ and $B$, with that name but written as $A \circ B$ instead of $A \otimes \mathbf{z} B$, is due to Whitney [27] in 1938. Tensor products of modules over a commutative ring are due to Bourbaki [2] in 1948.

## 2. Bilinear Maps

We already described the elements of $M \otimes_{R} N$ as sums (1.4) subject to the rules (1.2) and (1.3). The intention is that $M \otimes_{R} N$ is the "freest" object satisfying (1.2) and (1.3). The essence of (1.2) and (1.3) is bilinearity. What does that mean?

A function $B: M \times N \rightarrow P$, where $M, N$, and $P$ are $R$-modules, is called bilinear if it is linear (that is, $R$-linear) in each argument when the other one fixed:

$$
\begin{array}{ll}
B\left(m_{1}+m_{2}, n\right)=B\left(m_{1}, n\right)+B\left(m_{2}, n\right), & B(r m, n)=r B(m, n), \\
B\left(m, n_{1}+n_{2}\right)=B\left(m, n_{1}\right)+B\left(m, n_{2}\right), & B(m, r n)=r B(m, n) . \tag{2.2}
\end{array}
$$

So $B(-, n)$ is a linear map $M \rightarrow P$ for each $n$ and $B(m,-)$ is a linear map $N \rightarrow P$ for each $m$. In particular, $B(0, n)=0$ and $B(m, 0)=0$. Here are some examples of bilinear maps.
(1) The dot product $\mathbf{v} \cdot \mathbf{w}$ on $\mathbf{R}^{n}$ is a bilinear function $\mathbf{R}^{n} \times \mathbf{R}^{n} \rightarrow \mathbf{R}$. More generally, for $A \in \mathrm{M}_{n}(\mathbf{R})$ the function $\langle\mathbf{v}, \mathbf{w}\rangle=\mathbf{v} \cdot A \mathbf{w}$ is a bilinear map $\mathbf{R}^{n} \times \mathbf{R}^{n} \rightarrow \mathbf{R}$.
(2) Matrix multiplication $\mathrm{M}_{m, n}(\mathbf{R}) \times \mathrm{M}_{n, p}(\mathbf{R}) \rightarrow \mathrm{M}_{m, p}(\mathbf{R})$ is bilinear. The dot product is the special case $m=p=1$ (writing $\mathbf{v} \cdot \mathbf{w}$ as $\left.\mathbf{v}^{\top} \mathbf{w}\right)$.
(3) The cross product $\mathbf{v} \times \mathbf{w}$ is a bilinear function $\mathbf{R}^{3} \times \mathbf{R}^{3} \rightarrow \mathbf{R}^{3}$.
(4) The determinant det: $\mathrm{M}_{2}(R) \rightarrow R$ is a bilinear function of matrix columns.
(5) For an $R$-module $M$, scalar multiplication $R \times M \rightarrow M$ is bilinear.
(6) Multiplication $R \times R \rightarrow R$ is bilinear.
(7) Set the dual module of $M$ to be $M^{\vee}=\operatorname{Hom}_{R}(M, R)$. The dual pairing $M^{\vee} \times M \rightarrow R$ given by $(\varphi, m) \mapsto \varphi(m)$ is bilinear.
(8) For $\varphi \in M^{\vee}$ and $\psi \in N^{\vee}$, the map $M \times N \rightarrow R$ where $(m, n) \mapsto \varphi(m) \psi(n)$ is bilinear.
(9) If $M \times N \xrightarrow{B} P$ is bilinear and $P \xrightarrow{L} Q$ is linear, the composite $M \times N \xrightarrow{L \circ B} Q$ is bilinear. (This is a very important example. Check it!)
(10) From Section 1, the expression $m \otimes n$ is supposed to be bilinear in $m$ and $n$. That is, we want the function $M \times N \rightarrow M \otimes_{R} N$ given by $(m, n) \mapsto m \otimes n$ to be bilinear.
Here are a few examples of functions of two arguments that are not bilinear:
(1) For an $R$-module $M$, addition $M \times M \rightarrow M$, where $\left(m, m^{\prime}\right) \mapsto m+m^{\prime}$, is usually not bilinear: it is usually not additive in $m$ when $m^{\prime}$ is fixed (that is, $\left(m_{1}+m_{2}\right)+m^{\prime} \neq$ $\left(m_{1}+m^{\prime}\right)+\left(m_{2}+m^{\prime}\right)$ in general) or additive in $m^{\prime}$ when $m$ is fixed.

[^2](2) For $\varphi \in M^{\vee}$ and $\psi \in N^{\vee}$, the sum $M \times N \rightarrow R$ given by $(m, n) \mapsto \varphi(m)+\psi(n)$ is usually not bilinear.
(3) Treat $\mathrm{M}_{n}(\mathbf{C})$ as a $\mathbf{C}$-vector space. The function $\mathrm{M}_{n}(\mathbf{C}) \times \mathrm{M}_{n}(\mathbf{C}) \rightarrow \mathrm{M}_{n}(\mathbf{C})$ given by $(A, B) \mapsto A \bar{B}$ is not bilinear. It is biadditive (i.e., additive in each component when the other one is fixed) but look at how scalar multiplication behaves in the second component: for $z \in \mathbf{C}, A \overline{z B}$ is $\bar{z}(A \bar{B})$ rather than $z(A \bar{B})$.
Why write bilinear functions as $B: M \times N \rightarrow P$, not as $B: M \oplus N \rightarrow P$ ? Because we don't use a module structure on the domain. That's why for addition $R \times R \rightarrow R$ and multiplication $R \times R \rightarrow R$, we might write addition as $R \oplus R \rightarrow R$ (it is linear on $R \oplus R$ ) but we don't do that for multiplication: it's bilinear, but not linear, e.g., $\left(r+r^{\prime}\right)\left(s+s^{\prime}\right) \neq r s+r^{\prime} s^{\prime}$ in general. Linear functions are generalized additions and bilinear functions are generalized multiplications. Don't confuse a bilinear function on $M \times N$ with a linear function on $M \oplus N$.

For $R$-modules $M_{1}, \ldots, M_{k}$, a function $f: M_{1} \times \cdots \times M_{k} \rightarrow M$ is called multilinear or $k$-multilinear if $f\left(m_{1}, \ldots, m_{k}\right)$ is linear (that is, $R$-linear) in each $m_{i}$ when the other coordinates are fixed. So 2-multilinear means bilinear. Here are some multilinear functions:
(1) The scalar triple product $\mathbf{u} \cdot(\mathbf{v} \times \mathbf{w})$ is trilinear $\mathbf{R}^{3} \times \mathbf{R}^{3} \times \mathbf{R}^{3} \rightarrow \mathbf{R}$.
(2) The function $f(\mathbf{u}, \mathbf{v}, \mathbf{w})=(\mathbf{u} \cdot \mathbf{v}) \mathbf{w}$ is trilinear $\mathbf{R}^{n} \times \mathbf{R}^{n} \times \mathbf{R}^{n} \rightarrow \mathbf{R}^{n}$.
(3) The function $M^{\vee} \times M \times N \rightarrow N$ given by $(\varphi, m, n) \mapsto \varphi(m) n$ is trilinear.
(4) If $B: M \times N \rightarrow P$ and $B^{\prime}: P \times Q \rightarrow T$ are bilinear then $M \times N \times Q \rightarrow T$ by $(m, n, q) \mapsto B^{\prime}(B(m, n), q)$ is trilinear.
(5) Multiplication $R \times \cdots \times R \rightarrow R$ with $k$ factors is $k$-multilinear.
(6) The determinant det: $\mathrm{M}_{n}(R) \rightarrow R$, as a function of matrix columns, is $n$-multilinear.
(7) If $M_{1} \times \cdots \times M_{k} \xrightarrow{f} M$ is $k$-multilinear and $M \xrightarrow{L} N$ is linear then the composite $M_{1} \times \cdots \times M_{k} \xrightarrow{L \circ f} N$ is $k$-multilinear.
(8) For $f: \mathbf{R}^{m} \rightarrow \mathbf{R}^{n}$ and $\mathbf{x} \in \mathbf{R}^{m}$, the $k$ th derivative $\left(D^{k} f\right)_{\mathbf{x}}:\left(\mathbf{R}^{m}\right)^{k} \rightarrow \mathbf{R}^{n}$ is $k$ multilinear. (If you're unfamiliar with 1st derivatives as linear maps, ignore this.)
The $R$-linear maps $M \rightarrow N$ form an $R$-module $\operatorname{Hom}_{R}(M, N)$ under addition of functions and $R$-scaling. The $R$-bilinear maps $M \times N \rightarrow P$ form an $R$-module $\operatorname{Bil}_{R}(M, N ; P)$ in the same way. However, unlike linear maps, bilinear maps are missing some features:
(1) There is no "kernel" of a bilinear map $M \times N \rightarrow P$ since $M \times N$ is not a module.
(2) The image of a bilinear map $M \times N \rightarrow P$ need not form a submodule.

Example 2.1. Define $B: \mathbf{R}^{n} \times \mathbf{R}^{n} \rightarrow \mathbf{M}_{n}(\mathbf{R})$ by $B(\mathbf{v}, \mathbf{w})=\mathbf{v w}^{\top}$, where $\mathbf{v}$ and $\mathbf{w}$ are column vectors, so $\mathbf{v w}^{\top}$ is $n \times n$. For example, when $n=2$,

$$
B\left(\binom{a_{1}}{a_{2}},\binom{b_{1}}{b_{2}}\right)=\binom{a_{1}}{a_{2}}\left(b_{1}, b_{2}\right)=\left(\begin{array}{ll}
a_{1} b_{1} & a_{1} b_{2} \\
a_{2} b_{1} & a_{2} b_{2}
\end{array}\right) .
$$

Generally, if $\mathbf{v}=\sum a_{i} e_{i}$ and $\mathbf{w}=\sum b_{j} e_{j}$ in terms of the standard basis of $\mathbf{R}^{n}$, then $\mathbf{v w}{ }^{\top}$ is the $n \times n$ matrix $\left(a_{i} b_{j}\right)$. This matrix is $\mathbf{R}$-bilinear in $\mathbf{v}$ and $\mathbf{w}$, so $B$ is bilinear. For $n \geq 2$ the image of $B$ isn't closed under addition, so it isn't a subspace of $\mathrm{M}_{n}(\mathbf{R})$. Why? Each matrix $B(\mathbf{v}, \mathbf{w})$ has rank 1 (or 0 ) since its columns are scalar multiples of $\mathbf{v}$. The matrix

$$
B\left(e_{1}, e_{1}\right)+B\left(e_{2}, e_{2}\right)=e_{1} e_{1}^{\top}+e_{2} e_{2}^{\top}=\left(\begin{array}{cccc}
1 & 0 & \cdots & 0 \\
0 & 1 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0
\end{array}\right)
$$

has a 2-dimensional image, so $B\left(e_{1}, e_{1}\right)+B\left(e_{2}, e_{2}\right) \neq B(\mathbf{v}, \mathbf{w})$ for all $\mathbf{v}$ and $\mathbf{w}$ in $\mathbf{R}^{n}$. (Similarly, $\sum_{i=1}^{n} B\left(e_{i}, e_{i}\right)$ is the $n \times n$ identity matrix, which is not of the form $B(\mathbf{v}, \mathbf{w})$.)

## 3. Construction of the Tensor Product

A bilinear map $M \times N \rightarrow P$ to an $R$-module $P$ can be composed with a linear map $P \rightarrow Q$ to get a map $M \times N \rightarrow Q$ that is bilinear.

We will construct the tensor product of $M$ and $N$ as a solution to a universal mapping problem: find an $R$-module $T$ and bilinear map $b: M \times N \rightarrow T$ such that every bilinear map on $M \times N$ is the composite of the bilinear map $b$ and a unique linear map out of $T$.

This is analogous to the universal mapping property of the abelianization $G /[G, G]$ of a group $G$ : homomorphisms $G \longrightarrow A$ with abelian $A$ are "the same" as homomorphisms $G /[G, G] \longrightarrow A$ because every homomorphism $f: G \rightarrow A$ is the composite of the canonical homomorphism $\pi: G \rightarrow G /[G, G]$ with a unique homomorphism $\widetilde{f}: G /[G, G] \rightarrow A$.

Definition 3.1. The tensor product $M \otimes_{R} N$ is an $R$-module equipped with a bilinear map $M \times N \xrightarrow{\otimes} M \otimes_{R} N$ such that for each bilinear map $M \times N \xrightarrow{B} P$ there is a unique linear map $M \otimes_{R} N \xrightarrow{L} P$ making the following diagram commute.

While the functions in the universal mapping property for $G /[G, G]$ are all group homomorphisms (out of $G$ and $G /[G, G]$ ), functions in the universal mapping property for $M \otimes_{R} N$ are not all of the same type: those out of $M \times N$ are bilinear and those out of $M \otimes_{R} N$ are linear: bilinear maps out of $M \times N$ turn into linear maps out of $M \otimes_{R} N$.

The definition of the tensor product involves not just a new module $M \otimes_{R} N$, but also a special bilinear map to it, $\otimes: M \times N \rightarrow M \otimes_{R} N$. This is similar to the universal mapping property for the abelianization $G /[G, G]$, which requires not just $G /[G, G]$ but also the homomorphism $\pi: G \rightarrow G /[G, G]$ through which all homomorphisms from $G$ to abelian groups factor. The universal mapping property requires fixing this extra information.

Before building a tensor product, let's show any two tensor products are essentially the same. Let $R$-modules $T$ and $T^{\prime}$, and bilinear maps $M \times N \xrightarrow{b} T$ and $M \times N \xrightarrow{b^{\prime}} T^{\prime}$, satisfy the universal mapping property of the tensor product. From universality of $M \times N \xrightarrow{b} T$, the map $M \times N \xrightarrow{b^{\prime}} T^{\prime}$ factors uniquely through $T$ : a unique linear map $f: T \rightarrow T^{\prime}$ makes

commute. From universality of $M \times N \xrightarrow{b^{\prime}} T^{\prime}$, the map $M \times N \xrightarrow{b} T$ factors uniquely through $T^{\prime}$ : a unique linear map $f^{\prime}: T^{\prime} \rightarrow T$ makes

commute. We combine (3.1) and (3.2) into the commutative diagram

Removing the middle, we have the commutative diagram

From universality of $(T, b)$, a unique linear map $T \rightarrow T$ fits in (3.3). The identity map works, so $f^{\prime} \circ f=\mathrm{id}_{T}$. Similarly, $f \circ f^{\prime}=\mathrm{id}_{T^{\prime}}$ by stacking (3.1) and (3.2) together in the other order. Thus $T$ and $T^{\prime}$ are isomorphic $R$-modules by $f$ and also $f \circ b=b^{\prime}$, which means $f$ identifies $b$ with $b^{\prime}$. So two tensor products of $M$ and $N$ can be identified with each other in a unique way compatible ${ }^{6}$ with the distinguished bilinear maps to them from $M \times N$.

Theorem 3.2. A tensor product of $M$ and $N$ exists.
Proof. Consider $M \times N$ simply as a set. We form the free $R$-module on this set:

$$
F_{R}(M \times N)=\bigoplus_{(m, n) \in M \times N} R \delta_{(m, n)}
$$

(This is an enormous $R$-module. If $R=\mathbf{R}$ and $M=N=\mathbf{R}^{3}$ then $F_{R}(M \times N)$ is a direct sum of $\mathbf{R}^{6}$-many copies of $\mathbf{R}$. The direct sum runs over all pairs of vectors from $\mathbf{R}^{3}$, not just pairs coming from a basis of $\mathbf{R}^{3}$, and its components lie in $\mathbf{R}$. For most modules a basis doesn't even generally exist.) Let $D$ be the submodule of $F_{R}(M \times N)$ spanned by all the elements

$$
\begin{gathered}
\delta_{\left(m+m^{\prime}, n\right)}-\delta_{(m, n)}-\delta_{\left(m^{\prime}, n\right)}, \quad \delta_{\left(m, n+n^{\prime}\right)}-\delta_{(m, n)}-\delta_{\left(m, n^{\prime}\right)}, \quad \delta_{(r m, n)}-\delta_{(m, r n)} \\
r \delta_{(m, n)}-\delta_{(r m, n)}, \quad r \delta_{(m, n)}-\delta_{(m, r n)}
\end{gathered}
$$

The quotient module by $D$ will serve as the tensor product: set

$$
M \otimes_{R} N:=F_{R}(M \times N) / D
$$

We write the coset $\delta_{(m, n)}+D$ in $M \otimes_{R} N$ as $m \otimes n$.
From the definition of $D$, we get relations in $F_{R}(M \times N) / D$ like

$$
\delta_{\left(m+m^{\prime}, n\right)} \equiv \delta_{(m, n)}+\delta_{\left(m^{\prime}, n\right)} \bmod D,
$$

which is the same as

$$
\left(m+m^{\prime}\right) \otimes n=m \otimes n+m^{\prime} \otimes n
$$

in $M \otimes_{R} N$. Similarly, $m \otimes\left(n+n^{\prime}\right)=m \otimes n+m \otimes n^{\prime}$ and $r(m \otimes n)=r m \otimes n=m \otimes r n$ in $M \otimes_{R} N$. These relations are the reason $D$ was defined the way it was, and they show that the function $M \times N \xrightarrow{\otimes} M \otimes_{R} N$ given by $(m, n) \mapsto m \otimes n$ is bilinear. (No other function $M \times N \rightarrow M \otimes_{R} N$ will be considered except this one.)

Now we will show all bilinear maps out of $M \times N$ factor uniquely through the bilinear map $M \times N \rightarrow M \otimes_{R} N$ that we just wrote down. Suppose $P$ is an $R$-module and $M \times N \xrightarrow{B} P$ is a bilinear map. Treating $M \times N$ simply as a set, so $B$ is just a function on this set (ignore its bilinearity), the universal mapping property of free modules extends $B$ from a function

[^3]$M \times N \rightarrow P$ to a linear function $\ell: F_{R}(M \times N) \rightarrow P$ with $\ell\left(\delta_{(m, n)}\right)=B(m, n)$, so the diagram

commutes. We want to show $\ell$ makes sense as a function on $M \otimes_{R} N$, which means showing ker $\ell$ contains $D$. From the bilinearity of $B$,
\[

$$
\begin{gathered}
B\left(m+m^{\prime}, n\right)=B(m, n)+B\left(m, n^{\prime}\right), \quad B\left(m, n+n^{\prime}\right)=B(m, n)+B\left(m, n^{\prime}\right), \\
r B(m, n)=B(r m, n)=B(m, r n),
\end{gathered}
$$
\]

so

$$
\begin{gathered}
\ell\left(\delta_{\left(m+m^{\prime}, n\right)}\right)=\ell\left(\delta_{(m, n)}\right)+\ell\left(\delta_{\left(m^{\prime}, n\right)}\right), \quad \ell\left(\delta_{\left(m, n+n^{\prime}\right)}\right)=\ell\left(\delta_{(m, n)}\right)+\ell\left(\delta_{\left(m, n^{\prime}\right)}\right), \\
r \ell\left(\delta_{(m, n)}\right)=\ell\left(\delta_{(r m, n)}\right)=\ell\left(\delta_{(m, r n)}\right) .
\end{gathered}
$$

Since $\ell$ is linear, these conditions are the same as

$$
\begin{gathered}
\ell\left(\delta_{\left(m+m^{\prime}, n\right)}\right)=\ell\left(\delta_{(m, n)}+\delta_{\left(m^{\prime}, n\right)}\right), \quad \ell\left(\delta_{\left(m, n+n^{\prime}\right)}\right)=\ell\left(\delta_{(m, n)}+\delta_{\left(m, n^{\prime}\right)}\right), \\
\ell\left(r \delta_{(m, n)}\right)=\ell\left(\delta_{(r m, n)}\right)=\ell\left(\delta_{(m, r n)}\right) .
\end{gathered}
$$

Therefore the kernel of $\ell$ contains all the generators of the submodule $D$, so $\ell$ induces a linear map $L: F_{R}(M \times N) / D \rightarrow P$ where $L\left(\delta_{(m, n)}+D\right)=\ell\left(\delta_{(m, n)}\right)=B(m, n)$, which means the diagram

commutes. Since $F_{R}(M \times N) / D=M \otimes_{R} N$ and $\delta_{(m, n)}+D=m \otimes n$, the above diagram is

and that shows every bilinear map $B$ out of $M \times N$ comes from a linear map $L$ out of $M \otimes_{R} N$ such that $L(m \otimes n)=B(m, n)$ for all $m \in M$ and $n \in N$.

It remains to show the linear map $M \otimes_{R} N \xrightarrow{L} P$ in (3.4) is the only one that makes (3.4) commute. We go back to the definition of $M \otimes_{R} N$ as a quotient of the free module
$F_{R}(M \times N)$. From the construction of free modules, every element of $F_{R}(M \times N)$ is a finite sum

$$
r_{1} \delta_{\left(m_{1}, n_{1}\right)}+\cdots+r_{k} \delta_{\left(m_{k}, n_{k}\right)}
$$

The reduction map $F_{R}(M \times N) \rightarrow F_{R}(M \times N) / D=M \otimes_{R} N$ is linear, so every element of $M \otimes_{R} N$ is a finite sum

$$
\begin{equation*}
r_{1}\left(m_{1} \otimes n_{1}\right)+\cdots+r_{k}\left(m_{k} \otimes n_{k}\right) . \tag{3.5}
\end{equation*}
$$

This means the elements $m \otimes n$ in $M \otimes_{R} N$ span it as an $R$-module. Therefore linear maps out of $M \otimes_{R} N$ are completely determined by their values on all the elements $m \otimes n$, so there is at most one linear map $M \otimes_{R} N \rightarrow P$ with the effect $m \otimes n \mapsto B(m, n)$. We have created a linear map out of $M \otimes_{R} N$ with this very effect in (3.4), so it is the only one.

Having shown a tensor product of $M$ and $N$ exists, ${ }^{7}$ its essential uniqueness lets us call $M \otimes_{R} N$ "the" tensor product rather than "a" tensor product. Don't forget that the construction involves not only the module $M \otimes_{R} N$ but also the distinguished bilinear map $M \times N \xrightarrow{\otimes} M \otimes_{R} N$ given by $(m, n) \mapsto m \otimes n$, through which all bilinear maps out of $M \times N$ factor. We call this distinguished map the canonical bilinear map from $M \times N$ to the tensor product. Elements of $M \otimes_{R} N$ are called tensors, and will be denoted by the letter $t$. Tensors in $M \otimes_{R} N$ that have the form $m \otimes n$ are called elementary tensors. (Other names for elementary tensors are simple tensors, decomposable tensors, pure tensors, and monomial tensors.) Just as elements of the free $R$-module $F_{R}(A)$ on a set $A$ are usually not of the form $\delta_{a}$ but are linear combinations of these, elements of $M \otimes_{R} N$ are usually not elementary tensors ${ }^{8}$ but are linear combinations of elementary tensors. In fact each tensor is a sum of elementary tensors since $r(m \otimes n)=(r m) \otimes n$. This shows all elements of $M \otimes_{R} N$ have the form (1.4).

That every tensor is a sum of elementary tensors, but need not be an elementary tensor itself, is a feature that confuses people who are learning about tensor products. One source of the confusion is that in the direct sum $M \oplus N$ every element is a pair ( $m, n$ ), so why shouldn't every element of $M \otimes_{R} N$ have the form $m \otimes n$ ? Here are two related ideas to keep in mind, so it seems less strange that not all tensors are elementary.

- The $R$-module $R[X, Y]$ is a tensor product of $R[X]$ and $R[Y]$ (see Example 4.12) and, as Eisenbud and Harris note in their book on schemes [5, p. 39], the study of polynomials in two variables is more than the study of polynomials of the form $f(X) g(Y)$. That is, most polynomials in $R[X, Y]$ are not $f(X) g(Y)$, but they are all a sum of such products (and in fact they are sums of monomials $a_{i j} X^{i} Y^{j}$ ).

[^4]- The role of elementary tensors among all tensors is like that of separable solutions $f(x) g(y)$ to a 2 -variable PDE among all solutions. ${ }^{9}$ Solutions to a PDE may not be separable. First we determine the separable solutions and then the general solution as a sum (perhaps an infinite sum) of separable solutions.
From now on forget the explicit construction of $M \otimes_{R} N$ as the quotient of an enormous free module $F_{R}(M \times N)$. It will confuse you more than it's worth to try to think about $M \otimes_{R} N$ in terms of its construction. What is more important to remember is the universal mapping property of the tensor product, which we will start using systematically in the next section. To get used to the bilinearity of $\otimes$, let's prove two simple results.

Theorem 3.3. Let $M$ and $N$ be $R$-modules with respective spanning sets $\left\{x_{i}\right\}_{i \in I}$ and $\left\{y_{j}\right\}_{j \in J}$. The tensor product $M \otimes_{R} N$ is spanned linearly by the elementary tensors $x_{i} \otimes y_{j}$.
Proof. An elementary tensor in $M \otimes_{R} N$ has the form $m \otimes n$. Write $m=\sum_{i} a_{i} x_{i}$ and $n=\sum_{j} b_{j} y_{j}$, where the $a_{i}$ 's and $b_{j}$ 's are 0 for all but finitely many $i$ and $j$. From the bilinearity of $\otimes$,

$$
m \otimes n=\sum_{i} a_{i} x_{i} \otimes \sum_{j} b_{j} y_{j}=\sum_{i, j} a_{i} b_{j} x_{i} \otimes y_{j}
$$

is a linear combination of the tensors $x_{i} \otimes y_{j}$. So every elementary tensor is a linear combination of the particular elementary tensors $x_{i} \otimes y_{j}$. Since every tensor is a sum of elementary tensors, the $x_{i} \otimes y_{j}$ 's span $M \otimes_{R} N$ as an $R$-module.

Example 3.4. Let $e_{1}, \ldots, e_{k}$ be the standard basis of $R^{k}$. The $R$-module $R^{k} \otimes_{R} R^{k}$ is linearly spanned by the $k^{2}$ elementary tensors $e_{i} \otimes e_{j}$. We will see later (Theorem 4.9) that these elementary tensors are a basis of $R^{k} \otimes_{R} R^{k}$, which for $R$ a field is consistent with the physicist's "definition" of tensor products of vector spaces from Section 1 using bases.

Theorem 3.5. In $M \otimes_{R} N, m \otimes 0=0$ and $0 \otimes n=0$.
Proof. This is just like the proof that $a \cdot 0=0$ in a ring: since $m \otimes n$ is additive in $n$ with $m$ fixed, $m \otimes 0=m \otimes(0+0)=m \otimes 0+m \otimes 0$. Subtracting $m \otimes 0$ from both sides, $m \otimes 0=0$. That $0 \otimes n=0$ follows by a similar argument.

Example 3.6. If $A$ is a finite abelian group, $\mathbf{Q} \otimes_{\mathbf{Z}} A=0$ since every elementary tensor is 0 : for $a \in A$, let $n a=0$ for some positive integer $n$. Then in $\mathbf{Q} \otimes \mathbf{Z} A, r \otimes a=n(r / n) \otimes a=$ $r / n \otimes n a=r / n \otimes 0=0$. Every tensor is a sum of elementary tensors, and every elementary tensor is 0 , so all tensors are 0 . (For instance, $(1 / 3) \otimes(5 \bmod 7)=0$ in $\mathbf{Q} \otimes \mathbf{Z} \mathbf{Z} / 7 \mathbf{Z}$. Thus we can have $m \otimes n=0$ without $m$ or $n$ being 0 .)

To show $\mathbf{Q} \otimes_{\mathbf{Z}} A=0$, we don't need $A$ to be finite, but rather that each element of $A$ has finite order. The group $\mathbf{Q} / \mathbf{Z}$ has that property, so $\mathbf{Q} \otimes_{\mathbf{Z}}(\mathbf{Q} / \mathbf{Z})=0$. By a similar argument, $\mathbf{Q} / \mathbf{Z} \otimes \mathbf{Z} \mathbf{Q} / \mathbf{Z}=0$.

Since $M \otimes_{R} N$ is spanned additively by elementary tensors, each linear (or just additive) function out of $M \otimes_{R} N$ is determined on all tensors from its values on elementary tensors. This is why linear maps on tensor products are in practice described only by their values on elementary tensors. It is similar to describing a linear map between finite free modules

[^5]using a matrix. The matrix directly tells you only the values of the map on a particular basis, but this information is enough to determine the linear map everywhere.

However, there is a key difference between basis vectors and elementary tensors: elementary tensors have lots of linear relations. A linear map out of $\mathbf{R}^{2}$ is determined by its values on $(1,0),(2,3),(8,4)$, and $(-1,5)$, but those values are not independent: they have to satisfy every linear relation the four vectors satisfy because a linear map preserves linear relations. Similarly, a random function on elementary tensors generally does not extend to a linear map on the tensor product: elementary tensors span the tensor product of two modules, but they are not linearly independent.

Functions of elementary tensors can't be created out of a random function of two variables. For instance, the "functions" $M \otimes_{R} M \rightarrow M$ where $m \otimes m^{\prime} \mapsto m+m^{\prime}$ and $m \otimes m^{\prime} \mapsto m$ make no sense since $m \otimes m^{\prime}=(-m) \otimes\left(-m^{\prime}\right)$ but $m+m^{\prime}$ is usually not $-m-m^{\prime}$ and $m$ is usually not $-m$. The only good way to create linear maps out of $M \otimes_{R} N$ is by the universal mapping property of $M \otimes_{R} N$ (it creates linear maps from bilinear maps), since all linear relations among elementary tensors - from the obvious to the obscure - are built into the universal mapping property. A lot of practice with this is in Section 4. Understanding how the universal mapping property of $M \otimes_{R} N$ can be used to compute examples and to prove properties of tensor products is the best way to get used to tensor products; if you can't construct functions out of $M \otimes_{R} N$, then you don't understand $M \otimes_{R} N$.

The tensor product can be extended to allow more than two factors. Given $k$ modules $M_{1}, \ldots, M_{k}$, there is a module $M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ that is universal for $k$-multilinear maps: it admits a $k$-multilinear map $M_{1} \times \cdots \times M_{k} \xrightarrow{\otimes} M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ and every $k$-multilinear map out of $M_{1} \times \cdots \times M_{k}$ factors through this by composition with a unique linear map out of $M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ :

The image of $\left(m_{1}, \ldots, m_{k}\right)$ in $M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ is written $m_{1} \otimes \cdots \otimes m_{k}$. This $k$-fold tensor product can be constructed as a quotient of the free module $F_{R}\left(M_{1} \times \cdots \times M_{k}\right)$. It can also be constructed using tensor products of modules two at a time:

$$
\left(\cdots\left(\left(M_{1} \otimes_{R} M_{2}\right) \otimes_{R} M_{3}\right) \otimes_{R} \cdots\right) \otimes_{R} M_{k} .
$$

The canonical $k$-multilinear map to this $R$-module from $M_{1} \times \cdots \times M_{k}$ is $\left(m_{1}, \ldots, m_{k}\right) \mapsto$ $\left(\cdots\left(\left(m_{1} \otimes m_{2}\right) \otimes m_{3}\right) \cdots\right) \otimes m_{k}$. This is not the same construction of the $k$-fold tensor product using $F_{R}\left(M_{1} \times \cdots \times M_{k}\right)$, but it satisfies the same universal mapping property and thus can serve the same purpose (all constructions of a tensor product of $M_{1}, \ldots, M_{k}$ are isomorphic to each other in a unique way compatible with the distinguished $k$-multilinear maps to them from $M_{1} \times \cdots \times M_{k}$ ).

The module $M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ is spanned additively by all $m_{1} \otimes \cdots \otimes m_{k}$. Important examples of the $k$-fold tensor product are tensor powers $M^{\otimes k}$ of a single $R$-module $M$ :

$$
M^{\otimes 0}=R, \quad M^{\otimes 1}=M, \quad M^{\otimes 2}=M \otimes_{R} M, \quad M^{\otimes 3}=M \otimes_{R} M \otimes_{R} M,
$$

and so on. (The formula $M^{\otimes 0}=R$ is a convention, like $a^{0}=1$.)

Let's address a few beginner questions about the tensor product:
Questions
(1) What is $m \otimes n$ ?
(2) What does it mean to say $m \otimes n=0$ ?
(3) What does it mean to say $M \otimes_{R} N=0$ ?
(4) What does it mean to say $m_{1} \otimes n_{1}+\cdots+m_{k} \otimes n_{k}=m_{1}^{\prime} \otimes n_{1}^{\prime}+\cdots+m_{\ell}^{\prime} \otimes n_{\ell}^{\prime}$ ?
(5) How do tensor products make bilinear maps look like linear maps?
(6) Where do tensor products arise outside of mathematics?
(7) Is there a way to picture the tensor product?

## Answers

(1) Strictly speaking, $m \otimes n$ is the image of $(m, n) \in M \times N$ under the canonical bilinear map $M \times N \xrightarrow{\otimes} M \otimes_{R} N$ in the definition of the tensor product. Here's another answer, which is not a definition but more closely aligns with how $m \otimes n$ occurs in practice: $m \otimes n$ is that element of $M \otimes_{R} N$ at which the linear map $M \otimes_{R} N \rightarrow P$ corresponding to a bilinear map $M \times N \xrightarrow{B} P$ takes the value $B(m, n)$. Review the proof of Theorem 3.2 and check this property of $m \otimes n$ really holds.
(2) We have $m \otimes n=0$ if and only if every bilinear map out of $M \times N$ vanishes at $(m, n)$. Indeed, if $m \otimes n=0$ then for each bilinear map $B: M \times N \rightarrow P$ we have a commutative diagram

for some linear map $L$, so $B(m, n)=L(m \otimes n)=L(0)=0$. Conversely, if every bilinear map out of $M \times N$ sends $(m, n)$ to 0 then the canonical bilinear map $M \times N \rightarrow M \otimes_{R} N$, which is a particular example, sends $(m, n)$ to 0 . Since this bilinear map actually sends $(m, n)$ to $m \otimes n$, we obtain $m \otimes n=0$.

A very important consequence is a tip about how to show a particular elementary tensor $m \otimes n$ is not 0 : find a bilinear map $B$ out of $M \times N$ such that $B(m, n) \neq 0$. Remember this idea! It will be used in Theorem 4.9.

That $m \otimes 0=0$ and $0 \otimes n=0$ is related to $B(m, 0)=0$ and $B(0, n)=0$ for each bilinear map $B$ on $M \times N$. This gives another proof of Theorem 3.5.

As an exercise, check from the universal mapping property that $m_{1} \otimes \cdots \otimes m_{k}=0$ in $M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ if and only if all $k$-multilinear maps out of $M_{1} \times \cdots \times M_{k}$ vanish at $\left(m_{1}, \ldots, m_{k}\right)$.
(3) The tensor product $M \otimes_{R} N$ is 0 if and only if every bilinear map out of $M \times N$ (to all modules) is identically 0 . First suppose $M \otimes_{R} N=0$. Then all elementary tensors $m \otimes n$ are 0 , so $B(m, n)=0$ for all bilinear maps out of $M \times N$ by the answer to the second question. Thus $B$ is identically 0 . Next suppose every bilinear map out of $M \times N$ is identically 0 . Then the canonical bilinear map $M \times N \xrightarrow{\otimes} M \otimes_{R} N$, which is a particular example, is identically 0 . Since this function sends $(m, n)$ to
$m \otimes n$, we have $m \otimes n=0$ for all $m$ and $n$. Since $M \otimes_{R} N$ is additively spanned by all $m \otimes n$, the vanishing of all elementary tensors implies $M \otimes_{R} N=0$.

Returning to Example 3.6, that $\mathbf{Q} \otimes_{\mathbf{z}} A=0$ if each element of $A$ has finite order is another way of saying every $\mathbf{Z}$-bilinear map out of $\mathbf{Q} \times A$ is identically zero, which can be verified directly: if $B$ is such a map (into an abelian group) and $n a=0$ with $n \geq 1$, then $B(r, a)=B(n(r / n), a)=B(r / n, n a)=B(r / n, 0)=0$.

Turning this idea around, to show some tensor product module $M \otimes_{R} N$ is not 0 , find a bilinear map on $M \times N$ that is not identically 0 .
(4) We have $\sum_{i=1}^{k} m_{i} \otimes n_{i}=\sum_{j=1}^{\ell} m_{j}^{\prime} \otimes n_{j}^{\prime}$ if and only if for all bilinear maps $B$ out of $M \times N, \sum_{i=1}^{k} B\left(m_{i}, n_{i}\right)=\sum_{j=1}^{\ell} B\left(m_{j}^{\prime}, n_{j}^{\prime}\right)$. The justification is along the lines of the previous two answers and is left to the reader. For example, the condition $\sum_{i=1}^{k} m_{i} \otimes n_{i}=0$ means $\sum_{i=1}^{k} B\left(m_{i}, n_{i}\right)=0$ for all bilinear maps $B$ on $M \times N$.
(5) For a bilinear map $B: M \times N \rightarrow P$, its bilinearity is (2.1) and (2.2), which say

$$
\begin{array}{ll}
B\left(m_{1}+m_{2}, n\right)=B\left(m_{1}, n\right)+B\left(m_{2}, n\right), & B(r m, n)=r B(m, n), \\
B\left(m, n_{1}+n_{2}\right)=B\left(m, n_{1}\right)+B\left(m, n_{2}\right), & B(m, r n)=r B(m, n) .
\end{array}
$$

For the associated linear map $L: M \otimes_{R} N \rightarrow P$, the bilinearity of $B$ is the same as

$$
L\left(\left(m_{1}+m_{2}\right) \otimes n\right)=L\left(m_{1} \otimes n\right)+L\left(m_{2} \otimes n\right), \quad L((r m) \otimes n)=r L(m \otimes n)
$$

$$
L\left(m \otimes\left(n_{1}+n_{2}\right)\right)=L\left(m \otimes n_{1}\right)+L\left(m \otimes n_{2}\right), \quad L(m \otimes(r n))=r L(m \otimes n)
$$

Since $\left(m_{1}+m_{2}\right) \otimes n=m_{1} \otimes n+m_{2} \otimes n, m \otimes\left(n_{1}+n_{2}\right)=m \otimes n_{1}+m \otimes n_{2}$, $(r m) \otimes n=r(m \otimes n)$, and $m \otimes(r n)=r(m \otimes n)$, the four conditions on $L$ above are special cases of $L\left(t+t^{\prime}\right)=L(t)+L\left(t^{\prime}\right)$ and $L(r t)=r L(t)$, which is exactly what it means for $L$ to be linear.
(6) Tensors are used in physics and engineering (stress, elasticity, electromagnetism, metrics, diffusion MRI), where they transform in a multilinear way under a change in coordinates. The treatment of tensors in physics is discussed in Section 7.
(7) There isn't a simple picture of a tensor (even an elementary tensor) analogous to how a vector is an arrow. Some physical manifestations of tensors are in the previous answer, but they won't help you understand tensor products of modules.
Nobody is comfortable with tensor products at first. Two quotes by Cathy O'Neil and Johan de Jong ${ }^{10}$ nicely capture the phenomenon of learning about them:

- O'Neil: After a few months, though, I realized something. I hadn't gotten any better at understanding tensor products, but I was getting used to not understanding them. It was pretty amazing. I no longer felt anguished when tensor products came up; I was instead almost amused by their cunning ways.
- de Jong: It is the things you can prove that tell you how to think about tensor products. In other words, you let elementary lemmas and examples shape your intuition of the mathematical object in question. There's nothing else, no magical intuition will magically appear to help you "understand" it.

Remark 3.7. Hassler Whitney, who first defined tensor products beyond the setting of vector spaces, called abelian groups $A$ and $B$ a group pair relative to the abelian group $C$ if there is a Z-bilinear map $A \times B \rightarrow C$ and wrote [27, p. 499] that "any such group pair may be defined by choosing a homomorphism" $A \otimes_{\mathbf{z}} B \rightarrow C$. So the idea that $\otimes_{\mathbf{z}}$ solves a universal mapping problem is essentially due to Whitney.

[^6]
## 4. Examples of Tensor Products

Theorem 4.1. For positive integers $a$ and $b$ with $d=(a, b), \mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z} \cong \mathbf{Z} / d \mathbf{Z}$ as abelian groups. In particular, $\mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z}=0$ if and only if $(a, b)=1$.

Proof. Since 1 spans $\mathbf{Z} / a \mathbf{Z}$ and $\mathbf{Z} / b \mathbf{Z}, 1 \otimes 1$ spans $\mathbf{Z} / a \mathbf{Z} \otimes \mathbf{Z} \mathbf{Z} / b \mathbf{Z}$ by Theorem 3.3. From

$$
a(1 \otimes 1)=a \otimes 1=0 \otimes 1=0 \text { and } b(1 \otimes 1)=1 \otimes b=1 \otimes 0=0
$$

the additive order of $1 \otimes 1$ divides $a$ and $b$, and therefore also $d$, so $\left|\left(\mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z}\right)\right| \leq d$.
To show $\mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z}$ has size at least $d$, we create a $\mathbf{Z}$-linear map from $\mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z}$ onto $\mathbf{Z} / d \mathbf{Z}$. Since $d \mid a$ and $d \mid b$, we can reduce $\mathbf{Z} / a \mathbf{Z} \rightarrow \mathbf{Z} / d \mathbf{Z}$ and $\mathbf{Z} / b \mathbf{Z} \rightarrow \mathbf{Z} / d \mathbf{Z}$ in the natural way. Consider the map $\mathbf{Z} / a \mathbf{Z} \times \mathbf{Z} / b \mathbf{Z} \xrightarrow{B} \mathbf{Z} / d \mathbf{Z}$ that is reduction mod $d$ in each factor followed by multiplication: $B(x \bmod a, y \bmod b)=x y \bmod d$. This is $\mathbf{Z}$-bilinear, so the universal mapping property of the tensor product says there is a (unique) $\mathbf{Z}$-linear map $f: \mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z} \rightarrow \mathbf{Z} / d \mathbf{Z}$ making the diagram

commute, so $f(x \otimes y)=x y$. In particular, $f(x \otimes 1)=x$, so $f$ is onto. Therefore $\mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z}$ has size at least $d$, so the size is $d$ and we're done.

Example 4.2. The abelian group $\mathbf{Z} / 3 \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / 5 \mathbf{Z}$ is 0 . Such collapsing in a tensor product often bothers people when they first see it, but it's means something concrete: each $\mathbf{Z}$ bilinear map $B: \mathbf{Z} / 3 \mathbf{Z} \times \mathbf{Z} / 5 \mathbf{Z} \rightarrow A$ to an abelian group $A$ is identically 0 . That's easy to show directly: $3 B(a, b)=B(3 a, b)=B(0, b)=0$ and $5 B(a, b)=B(a, 5 b)=B(a, 0)=0$, so $B(a, b)$ is killed by $3 \mathbf{Z}+5 \mathbf{Z}=\mathbf{Z}$. Thus $B(a, b)$ is killed by 1 , which means $B(a, b)=0$.

In $\mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z}$ all tensors are elementary tensors: $x \otimes y=x y(1 \otimes 1)$ and a sum of multiples of $1 \otimes 1$ is again a multiple, so $\mathbf{Z} / a \mathbf{Z} \otimes \mathbf{Z} \mathbf{Z} / b \mathbf{Z}=\mathbf{Z}(1 \otimes 1)=\{x \otimes 1: x \in \mathbf{Z}\}$.

Note how the map $f: \mathbf{Z} / a \mathbf{Z} \otimes_{\mathbf{Z}} \mathbf{Z} / b \mathbf{Z} \rightarrow \mathbf{Z} / d \mathbf{Z}$ in the proof of Theorem 4.1 was created from the bilinear map $B: \mathbf{Z} / a \mathbf{Z} \times \mathbf{Z} / b \mathbf{Z} \rightarrow \mathbf{Z} / d \mathbf{Z}$ and the universal mapping property of tensor products. To define a linear map out of $M \otimes_{R} N$ sending all elementary tensors $m \otimes n$ to specific places, always back up and start by defining a bilinear map out of $M \times N$ sending $(m, n)$ to the place you want $m \otimes n$ to go. Make sure you show that map is bilinear! Then the universal mapping property of the tensor product gives you a linear map out of $M \otimes_{R} N$ sending $m \otimes n$ to the place where $(m, n)$ goes. As an anonymous student once wrote, "If you don't know what to do on a tensor products problem, build a well-chosen bilinear map out of $M \times N$ because there's basically nothing else you can do."

Theorem 4.3. For ideals $I$ and $J$ in $R$, there is a unique $R$-module isomorphism

$$
R / I \otimes_{R} R / J \cong R /(I+J)
$$

where $\bar{x} \otimes \bar{y} \mapsto \overline{x y}$. In particular, taking $I=J=0, R \otimes_{R} R \cong R$ by $x \otimes y \mapsto x y$.
For $R=\mathbf{Z}$ and nonzero $I$ and $J$, this is Theorem 4.1.

Proof. Start with the function $R / I \times R / J \rightarrow R /(I+J)$ given by $(x \bmod I, y \bmod J) \mapsto$ $x y \bmod I+J$. This is well-defined and bilinear, so from the universal mapping property of the tensor product we get a linear map $f: R / I \otimes_{R} R / J \rightarrow R /(I+J)$ making the diagram

commute, so $f(x \bmod I \otimes y \bmod J)=x y \bmod I+J$. To write down the inverse map, let $R \rightarrow R / I \otimes_{R} R / J$ by $r \mapsto r(\overline{1} \otimes \overline{1})$. This is linear, and when $r \in I$ the value is $\bar{r} \otimes \overline{1}=\overline{0} \otimes \overline{1}=0$. Similarly, when $r \in J$ the value is 0 . Therefore $I+J$ is in the kernel, so we get a linear $\operatorname{map} g: R /(I+J) \rightarrow R / I \otimes_{R} R / J$ by $g(r \bmod I+J)=r(\overline{1} \otimes \overline{1})=\bar{r} \otimes \overline{1}=\overline{1} \otimes \bar{r}$.

To check $f$ and $g$ are inverses, a computation in one direction shows

$$
f(g(r \bmod I+J))=f(\bar{r} \otimes \overline{1})=r \bmod I+J
$$

To show $g(f(t))=t$ for all $t \in R / I \otimes_{R} R / J$, we show each tensor is a scalar multiple of $\overline{1} \otimes \overline{1}$. An elementary tensor is $\bar{x} \otimes \bar{y}=x \overline{1} \otimes y \overline{1}=x y(\overline{1} \otimes \overline{1})$, so sums of elementary tensors are multiples of $\overline{1} \otimes \overline{1}$ and thus all tensors are multiples of $\overline{1} \otimes \overline{1}$. We have

$$
g(f(r(\overline{1} \otimes \overline{1})))=r g(1 \bmod I+J)=r(\overline{1} \otimes \overline{1})
$$

Remark 4.4. For ideals $I$ and $J$, a few operations produce new ideals: $I+J, I \cap J$, and $I J$. The intersection $I \cap J$ is the kernel of the linear map $R \rightarrow R / I \oplus R / J$ where $r \mapsto(\bar{r}, \bar{r})$. Theorem 4.3 tells us $I+J$ is the kernel of the linear map $R \rightarrow R / I \otimes_{R} R / J$ where $r \mapsto r(\overline{1} \otimes \overline{1})$.

Theorem 4.5. For an ideal $I$ in $R$ and $R$-module $M$, there is a unique $R$-module isomorphism

$$
(R / I) \otimes_{R} M \cong M / I M
$$

such that $\bar{r} \otimes m \mapsto \overline{r m}$. In particular, taking $I=(0), R \otimes_{R} M \cong M$ by $r \otimes m \mapsto r m$, so $R \otimes_{R} R \cong R$ as $R$-modules by $r \otimes r^{\prime} \mapsto r r^{\prime}$.

Proof. We start with the bilinear map $(R / I) \times M \rightarrow M / I M$ given by $(\bar{r}, m) \mapsto \overline{r m}$. From the universal mapping property of the tensor product, we get a linear map $f:(R / I) \otimes_{R} M \rightarrow$ $M / I M$ where $f(\bar{r} \otimes m)=\overline{r m}$.

To create an inverse map, start with the function $M \rightarrow(R / I) \otimes_{R} M$ given by $m \mapsto \overline{1} \otimes m$. This is linear in $m$ (check!) and kills $I M$ (generators for $I M$ are products $i m$ for $i \in I$
and $m \in M$, and $\overline{1} \otimes r m=\bar{i} \otimes m=\overline{0} \otimes m=0$, so it induces a linear map $g: M / I M \rightarrow$ $(R / I) \otimes_{R} M$ given by $g(\bar{m})=\overline{1} \otimes m$.

To check $f(g(\bar{m}))=\bar{m}$ and $g(f(t))=t$ for all $\bar{m} \in M / I M$ and $t \in(R / I) \otimes_{R} M$, we do the first one by a direct computation:

$$
f(g(\bar{m}))=f(\overline{1} \otimes m)=\overline{1 \cdot m}=\bar{m}
$$

To show $g(f(t))=t$ for all $t \in M \otimes_{R} N$, we show all tensors in $R / I \otimes_{R} M$ are elementary. An elementary tensor looks like $\bar{r} \otimes m=\overline{1} \otimes r m$, and a sum of tensors $\overline{1} \otimes m_{i}$ is $\overline{1} \otimes \sum_{i} m_{i}$. Thus all tensors look like $\overline{1} \otimes m$. We have $g(f(\overline{1} \otimes m))=g(\bar{m})=\overline{1} \otimes m$.

Example 4.6. For every abelian group $A,(\mathbf{Z} / n \mathbf{Z}) \otimes_{\mathbf{Z}} A \cong A / n A$ as abelian groups by $\bar{m} \otimes a \mapsto \overline{m a}$.

Remark 4.7. That $R \otimes_{R} M \cong M$ by $r \otimes m \mapsto r m$ says $R$-bilinear maps $B$ out of $R \times M$ can be identified with $R$-linear maps out of $M$, since $B(r, m)=B(1, r m)$ by bilinearity and $B(1,-)$ is linear in the second component.

Remark 4.8. For an ideal $I$ in $R$ and $R$-module $M$ there is an $R$-linear map $I \otimes_{R} M \rightarrow$ $I M$ where $i \otimes m \mapsto i m$, and it's surjective $(I M$ is spanned by all $i m$, which are in the image), but not necessarily injective! If $R=\mathbf{Z}, I=a \mathbf{Z}$, and $M=\mathbf{Z} / a \mathbf{Z}$ for $a \geq 2$ then $I \otimes_{R} M=(a \mathbf{Z}) \otimes_{\mathbf{Z}}(\mathbf{Z} / a \mathbf{Z}) \cong \mathbf{Z} / a \mathbf{Z}$ by $(a x) \otimes(y \bmod a) \mapsto x y \bmod a$, but $I M=\{0\}$.

In this section so far, $M$ or $N$ in $M \otimes_{R} N$ has been $R$ or $R / I$. Such a module contains 1 or $\overline{1}$, making all tensors in $M \otimes_{R} N$ elementary. Don't be misled. Most tensors are not elementary, and don't think $m \otimes n=m n(1 \otimes 1) ; 1$ is not in a general module, so $1 \otimes 1$ usually doesn't make sense. ${ }^{11}$ The next theorem, which justifies the discussion in the introduction about bases for tensor products of free modules, will let us construct nonelementary tensors.

Theorem 4.9. If $F$ and $F^{\prime}$ are free $R$-modules, with respective bases $\left\{e_{i}\right\}_{i \in I}$ and $\left\{e_{j}^{\prime}\right\}_{j \in J}$, then $F \otimes_{R} F^{\prime}$ is a free $R$-module with basis $\left\{e_{i} \otimes e_{j}^{\prime}\right\}_{(i, j) \in I \times J}$.
Proof. The result is clear if $F$ or $F^{\prime}$ is 0 , so let them both be nonzero modules (hence $R \neq 0$ and $I$ and $J$ are nonempty). By Theorem $3.3,\left\{e_{i} \otimes e_{j}^{\prime}\right\}$ spans $F \otimes_{R} F^{\prime}$ as an $R$-module.

To show this spanning set is linearly independent, suppose $\sum_{i, j} c_{i j} e_{i} \otimes e_{j}^{\prime}=0$, where all but finitely many $c_{i j}$ are 0 . We want to show every $c_{i j}$ is 0 . Pick two basis vectors $e_{i_{0}}$ and $e_{j_{0}}^{\prime}$ in $F$ and $F^{\prime}$. To show the coefficient $c_{i_{0} j_{0}}$ is 0 , consider the bilinear function $F \times F^{\prime} \rightarrow R$ by $(v, w) \mapsto v_{i_{0}} w_{j_{0}}$, where $v=\sum_{i} v_{i} e_{i}$ and $w=\sum_{j} w_{j} e_{j}^{\prime}$. (Here $v_{i}$ and $w_{j}$ are coordinates in $R$.) By the universal mapping property of tensor products there is a linear $\operatorname{map} f_{0}: F \otimes_{R} F^{\prime} \rightarrow R$ such that $f_{0}(v \otimes w)=v_{i_{0}} w_{j_{0}}$ on each elementary tensor $v \otimes w$.

[^7]In particular, $f_{0}\left(e_{i_{0}} \otimes e_{j_{0}}^{\prime}\right)=1$ and $f_{0}\left(e_{i} \otimes e_{j}^{\prime}\right)=0$ for $(i, j) \neq\left(i_{0}, j_{0}\right)$. Applying $f_{0}$ to the equation $\sum_{i, j} c_{i j} e_{i} \otimes e_{j}^{\prime}=0$ in $F \otimes_{R} F^{\prime}$ tells us $c_{i_{0} j_{0}}=0$ in $R$. Since $i_{0}$ and $j_{0}$ are arbitrary, all the coefficients are 0 .

Theorem 4.9 can be interpreted in terms of bilinear maps out of $F \times F^{\prime}$. It says that all bilinear maps out of $F \times F^{\prime}$ are determined by their values on the pairs $\left(e_{i}, e_{j}^{\prime}\right)$, and that each assignment of values to these pairs extends in a unique way to a bilinear map out of $F \times F^{\prime}$. (The uniqueness of the extension is connected to the linear independence of the elementary tensors $e_{i} \otimes e_{j}^{\prime}$.) This is the bilinear analogue of the existence and uniqueness of a linear extension of a function from a basis of a free module to the whole module.

Example 4.10. Let $K$ be a field and $V$ and $W$ be nonzero vector spaces over $K$ with finite dimension. There are bases for $V$ and $W$, say $\left\{e_{1}, \ldots, e_{m}\right\}$ for $V$ and $\left\{f_{1}, \ldots, f_{n}\right\}$ for $W$. Every element of $V \otimes_{K} W$ can be written in the form $\sum_{i, j} c_{i j} e_{i} \otimes f_{j}$ for unique $c_{i j} \in K$. In fact, this holds even for infinite-dimensional vector spaces, since Theorem 4.9 had no assumption that bases were finite. This justifies the description on the first page of tensor products of vector spaces using bases.
Example 4.11. For $R \neq 0$, let $F$ and $F^{\prime}$ be finite free $R$-modules of rank $\geq 2$ with bases $\left\{e_{1}, \ldots, e_{m}\right\}$ and $\left\{e_{1}^{\prime}, \ldots, e_{n}^{\prime}\right\}$. In $F \otimes_{R} F^{\prime}, e_{1} \otimes e_{1}^{\prime}+e_{2} \otimes e_{2}^{\prime}$ is a tensor that is provably not an elementary tensor. An elementary tensor in $F \otimes_{R} F^{\prime}$ has the form

$$
\begin{equation*}
\sum_{i=1}^{m} a_{i} e_{i} \otimes \sum_{j=1}^{n} b_{j} e_{j}^{\prime}=\sum_{i=1}^{m} \sum_{j=1}^{n} a_{i} b_{j} e_{i} \otimes e_{j}^{\prime} . \tag{4.1}
\end{equation*}
$$

The set of all $e_{i} \otimes e_{j}^{\prime}$ is a basis of $F \otimes_{R} F^{\prime}$ (Theorem 4.9), so if $e_{1} \otimes e_{1}^{\prime}+e_{2} \otimes e_{2}^{\prime}$ equals (4.1) for some $a_{i}$ and $b_{j}$, then by comparing coefficients

$$
a_{1} b_{1}=1, \quad a_{1} b_{2}=0, \quad a_{2} b_{1}=0, \quad a_{2} b_{2}=1 .
$$

Since $a_{1} b_{1}=1$ and $a_{2} b_{2}=1, a_{1}$ and $b_{2}$ are invertible, contradicting $a_{1} b_{2}=0$. So $e_{1} \otimes e_{1}^{\prime}+$ $e_{2} \otimes e_{2}^{\prime}$ is not an elementary tensor. Similarly, $e_{1} \otimes e_{2}^{\prime}+e_{2} \otimes e_{1}^{\prime}$ is not an elementary tensor. ${ }^{12}$

Example 4.12. For $R \neq 0, R[X] \otimes_{R} R[Y]$ is a free $R$-module with basis $\left\{X^{i} \otimes Y^{j}\right\}_{i, j \geq 0}$, so $R[X] \otimes_{R} R[Y]$ is isomorphic to $R[X, Y]$ as $R$-modules by $\sum c_{i j}\left(X^{i} \otimes Y^{j}\right) \mapsto \sum c_{i j} X^{i} Y^{j}$. More generally, $R\left[X_{1}, \ldots, X_{k}\right] \cong R[X]^{\otimes k}$ as $R$-modules with $X_{i}$ corresponding to the tensor $1 \otimes \cdots \otimes X \otimes \cdots \otimes 1$ where $X$ is in the $i$ th position. The difference between ordinary products and tensor products is like the difference between multiplying one-variable polynomials as $f(T) g(T)$ and as $f(X) g(Y)$.
Example 4.13. We return to Example 2.1. For $\mathbf{v}$ and $\mathbf{w}$ in $\mathbf{R}^{n}, B(\mathbf{v}, \mathbf{w})=\mathbf{v w}^{\top} \in \mathrm{M}_{n}(\mathbf{R})$. This is $\mathbf{R}$-bilinear, so there is an $\mathbf{R}$-linear map $L: \mathbf{R}^{n} \otimes_{\mathbf{R}} \mathbf{R}^{n} \rightarrow \mathrm{M}_{n}(\mathbf{R})$ where $L(\mathbf{v} \otimes \mathbf{w})=$ $\mathbf{v w}^{\top}$ for all elementary tensors $\mathbf{v} \otimes \mathbf{w}$. In Example 2.1 we saw that, for $n \geq 2$, the image of $B$ in $\mathrm{M}_{n}(\mathbf{R})$ is not closed under addition. In particular, $B\left(e_{1}, e_{1}\right)+B\left(e_{2}, e_{2}\right)$ is not of the form $B(\mathbf{v}, \mathbf{w})$. This is a typical "problem" with bilinear maps. However, using tensor products, $B\left(e_{1}, e_{1}\right)+B\left(e_{2}, e_{2}\right)=L\left(e_{1} \otimes e_{1}\right)+L\left(e_{2} \otimes e_{2}\right)=L\left(e_{1} \otimes e_{1}+e_{2} \otimes e_{2}\right)$, which is a value of $L$.

[^8]In fact, $L$ is an isomorphism. To prove this we use bases. By Theorem 4.9, $\mathbf{R}^{n} \otimes_{\mathbf{R}} \mathbf{R}^{n}$ has the basis $\left\{e_{i} \otimes e_{j}\right\}$. The value $L\left(e_{i} \otimes e_{j}\right)=e_{i} e_{j}^{\top}$ is the matrix with 1 in the $(i, j)$ entry and 0 elsewhere, and these matrices are the standard basis of $\mathrm{M}_{n}(\mathbf{R})$. Therefore $L$ sends a basis to a basis, so it is an isomorphism of $\mathbf{R}$-vector spaces.

Theorem 4.14. Let $F$ be a free $R$-module with basis $\left\{e_{i}\right\}_{i \in I}$. For $k \geq 1$, the $k$ th tensor power $F^{\otimes k}$ is free with basis $\left\{e_{i_{1}} \otimes \cdots \otimes e_{i_{k}}\right\}_{\left(i_{1}, \ldots, i_{k}\right) \in I^{k}}$.

Proof. This is similar to the proof of Theorem 4.9.
Theorem 4.15. If $M$ is an $R$-module and $F$ is a free $R$-module with basis $\left\{e_{i}\right\}_{i \in I}$, then every element of $M \otimes_{R} F$ has a unique representation in the form $\sum_{i \in I} m_{i} \otimes e_{i}$, where all but finitely many $m_{i}$ equal 0 .

Proof. This is vacuously true if $F=0(I=\emptyset)$, so take $F \neq 0$ (thus $R \neq 0)$. Using $M$ as a spanning set for $M$ and $\left\{e_{i}\right\}_{i \in I}$ as a spanning set for $F$, by Theorem 3.3 each element of $M \otimes_{R} F$ is a linear combination of elementary tensors $m_{i} \otimes e_{i}$, where $m_{i} \in M$. Since $r\left(m_{i} \otimes e_{i}\right)=\left(r m_{i}\right) \otimes e_{i}$, we can write every tensor in $M \otimes_{R} F$ as a sum of elementary tensors of the form $m_{i} \otimes e_{i}$. So we have a surjective linear map $f: \bigoplus_{i \in I} M \mapsto M \otimes_{R} F$ given by $f\left(\left(m_{i}\right)_{i \in I}\right)=\sum_{i \in I} m_{i} \otimes e_{i}$. (All but finitely many $m_{i}$ are 0 , so the sum makes sense.)

To create an inverse to $f$, consider the function $M \times F \rightarrow \bigoplus_{i \in I} M$ where $\left(m, \sum_{i} r_{i} e_{i}\right) \mapsto$ $\left(r_{i} m\right)_{i \in I}$. This function is bilinear (check!), so there is a linear map $g: M \otimes_{R} F \rightarrow \bigoplus_{i \in I} M$ where $g\left(m \otimes \sum_{i} r_{i} e_{i}\right)=\left(r_{i} m\right)_{i \in I}$.

To check $f(g(t))=t$ for all $t$ in $M \otimes_{R} F$, we can't expect that all tensors in $M \otimes_{R} F$ are elementary (an idea used in the proofs of Theorems 4.3 and 4.5), but we only need to check $f(g(t))=t$ when $t$ is an elementary tensor since $f$ and $g$ are additive and the elementary tensors additively span $M \otimes_{R} F$. (We will use this kind of argument $a$ lot to reduce the proof of an identity involving functions of all tensors to the case of elementary tensors even though most tensors are not themselves elementary. The point is all tensors are sums of elementary tensors and the formula we want to prove will involve additive functions.) An elementary tensor looks like $m \otimes \sum_{i} r_{i} e_{i}$, and

$$
\begin{aligned}
f\left(g\left(m \otimes \sum_{i \in I} r_{i} e_{i}\right)\right) & =f\left(\left(r_{i} m\right)_{i \in I}\right) \\
& =\sum_{i \in I} r_{i} m \otimes e_{i} \\
& =\sum_{i \in I} m \otimes r_{i} e_{i} \\
& =m \otimes \sum_{i \in I} r_{i} e_{i} .
\end{aligned}
$$

These sums have finitely many terms ( $r_{i}=0$ for all but finitely many $i$ ), from the definition of direct sums. Thus $f(g(t))=t$ for all $t \in M \otimes_{R} F$.

For the composition in the other order,

$$
g\left(f\left(\left(m_{i}\right)_{i \in I}\right)\right)=g\left(\sum_{i \in I} m_{i} \otimes e_{i}\right)=\sum_{i \in I} g\left(m_{i} \otimes e_{i}\right)=\sum_{i \in I}\left(\ldots, 0, m_{i}, 0, \ldots\right)=\left(m_{i}\right)_{i \in I} .
$$

Now that we know $M \otimes_{R} F \cong \bigoplus_{i \in I} M$, with $\sum_{i \in I} m_{i} \otimes e_{i}$ corresponding to $\left(m_{i}\right)_{i \in I}$, the uniqueness of coordinates in the direct sum implies the sum representation $\sum_{i \in I} m_{i} \otimes e_{i}$ is unique.
Example 4.16. For a ring $S \supset R$, elements of $S \otimes_{R} R[X]$ have unique expressions of the form $\sum_{n \geq 0} s_{n} \otimes X^{n}$, so $S \otimes_{R} R[X] \cong S[X]$ as $R$-modules by $\sum_{n \geq 0} s_{n} \otimes X^{n} \mapsto \sum_{n \geq 0} s_{n} X^{n}$.
Remark 4.17. When $f$ and $g$ are additive functions you can check $f(g(t))=t$ for all tensors $t$ by only checking it on elementary tensors, but it would be wrong to think you have proved injectivity of a linear map $f: M \otimes_{R} N \rightarrow P$ by only looking at elementary tensors. ${ }^{13}$ That is, if $f(m \otimes n)=f\left(m^{\prime} \otimes n^{\prime}\right) \Rightarrow m \otimes n=m^{\prime} \otimes n^{\prime}$, then it is not always true that $f(t)=f\left(t^{\prime}\right) \Rightarrow t=t^{\prime}$ for all $t$ and $t^{\prime}$ in $M \otimes_{R} N$, since injectivity of a linear map is not an additive property. ${ }^{14}$ This is the main reason that proving that a linear map out of a tensor product is injective can require technique. As a special case, if you want to prove a linear map out of a tensor product is an isomorphism, it might be easier to construct an inverse map and check the composite in both orders is the identity than to show the original map is injective and surjective.
Theorem 4.18. If $M$ is a nonzero finitely generated $R$-module then $M^{\otimes k} \neq 0$ for all $k$.
Proof. Necessarily $R \neq 0$. Write $M=R x_{1}+\cdots+R x_{d}$ for minimal $d \geq 1$. Set $N=$ $R x_{1}+\cdots+R x_{d-1}(N=0$ if $d=1)$, so $M=N+R x_{d}$ and $x_{d} \notin N$. Set $I=\left\{r \in R: r x_{d} \in N\right\}$, so $I$ is an ideal in $R$ and $1 \notin I$, so $I$ is a proper ideal. When we write an element $m$ of $M$ in the form $n+r x$ with $n \in N$ and $r \in R, n$ and $r$ may not be well-defined from $m$ but the value of $r \bmod I$ is well-defined: if $n+r x=n^{\prime}+r^{\prime} x$ then $\left(r-r^{\prime}\right) x=n^{\prime}-n \in N$, so $r \equiv r^{\prime} \bmod I$. Therefore the function $M^{k} \rightarrow R / I$ given by

$$
\left(n_{1}+r_{1} x_{d}, \ldots, n_{k}+r_{k} x_{d}\right) \mapsto r_{1} \cdots r_{d} \bmod I
$$

is well-defined and multilinear (check!), so there is an $R$-linear map $M^{\otimes k} \rightarrow R / I$ such that $\underbrace{x_{d} \otimes \cdots \otimes x_{d}}_{k \text { terms }} \mapsto 1 \bmod I \neq 0$. That shows $M^{\otimes k} \neq 0$.
Example 4.19. By Theorem 4.1, $(\mathbf{Z} / a \mathbf{Z})^{\otimes 2} \cong \mathbf{Z} / a \mathbf{Z}$ as $\mathbf{Z}$-modules.
Example 4.20. Tensor powers of a non-finitely generated module could vanish: $(\mathbf{Q} / \mathbf{Z})^{\otimes 2}=$ 0 as a $\mathbf{Z}$-module (Example 3.6). This example is interesting because $\mathbf{Q} / \mathbf{Z}$ is the union of cyclic subgroups $(1 / a) \mathbf{Z} / \mathbf{Z}$ for all $a \geq 1$, and each $(1 / a) \mathbf{Z} / \mathbf{Z}$ has a nonzero tensor square: $((1 / a) \mathbf{Z} / \mathbf{Z})^{\otimes 2} \cong(1 / a) \mathbf{Z} / \mathbf{Z}$ by an argument like the one used to prove Theorem 4.1. That $((1 / a) \mathbf{Z} / \mathbf{Z})^{\otimes 2} \neq 0$ while $(\mathbf{Q} / \mathbf{Z})^{\otimes 2}=0$ reflects something about bilinear maps: there are $\mathbf{Z}$-bilinear maps out of $(1 / a) \mathbf{Z} / \mathbf{Z} \times(1 / a) \mathbf{Z} / \mathbf{Z}$ that are not identically 0 , but every $\mathbf{Z}$-bilinear map out of $\mathbf{Q} / \mathbf{Z} \times \mathbf{Q} / \mathbf{Z}$ is identically 0 . For example, the $\mathbf{Z}$ bilinear map $(1 / 5) \mathbf{Z} / \mathbf{Z} \times(1 / 5) \mathbf{Z} / \mathbf{Z} \rightarrow \mathbf{Z} / 5 \mathbf{Z}$ given by $(x / 5, y / 5) \mapsto x y \bmod 5$ is nonzero at $(1 / 5,1 / 5)$, but each bilinear map $B$ out of $\mathbf{Q} / \mathbf{Z} \times \mathbf{Q} / \mathbf{Z}$ must vanish at $(1 / 5,1 / 5)$ since $B(1 / 5,1 / 5)=B(1 / 5,5 / 25)=B(5 / 5,1 / 25)=B(1,1 / 25)=B(0,1 / 25)=0$. Thus $(1 / 5) \otimes(1 / 5) \neq 0$ in $((1 / 5) \mathbf{Z} / \mathbf{Z})^{\otimes 2}$ while $(1 / 5) \otimes(1 / 5)=0$ in $(\mathbf{Q} / \mathbf{Z})^{\otimes 2}$. The lesson is that an elementary tensor requires context (which tensor product module is it in?).

The rest of this section is about tensor products when $R$ is a domain, so $R \neq 0$.

[^9]Theorem 4.21. Let $R$ be a domain with fraction field $K$ and $V$ be a $K$-vector space. There is an $R$-module isomorphism $K \otimes_{R} V \cong V$, where $x \otimes v \mapsto x v$.

By Theorem 4.5, $K \otimes_{K} V \cong V$ by $x \otimes v \mapsto x v$, but Theorem 4.21 is different because the scalars in the tensor product are from $R$.

Proof. Multiplication is a function $K \times V \rightarrow V$. It is $R$-bilinear, so the universal mapping property of tensor products says there is an $R$-linear function $f: K \otimes_{R} V \rightarrow V$ where $f(x \otimes v)=x v$ on elementary tensors. That says the diagram

commutes, where the lower diagonal map is scalar multiplication. Since $f(1 \otimes v)=v, f$ is onto.

To show $f$ is one-to-one, first we show every tensor in $K \otimes_{R} V$ is elementary with 1 in the first component. For an elementary tensor $x \otimes v$, write $x=a / b$ with $a$ and $b$ in $R$, and $b \neq 0$. Then

$$
x \otimes v=\frac{a}{b} \otimes v=\frac{1}{b} \otimes a v=\frac{1}{b} \otimes \frac{a b}{b} v=\frac{1}{b} b \otimes \frac{a}{b} v=1 \otimes \frac{a}{b} v=1 \otimes x v .
$$

Notice how we moved $x \in K$ across $\otimes$ even though $x$ need not be in $R$ : we used $K$-scaling in $V$ to create $b$ and $1 / b$ on the right side of $\otimes$ and bring $b$ across $\otimes$ from right to left, which cancels $1 / b$ on the left side of $\otimes$. This has the effect of moving $1 / b$ from left to right.

Thus all elementary tensors in $K \otimes_{R} V$ have the form $1 \otimes v$ for some $v \in V$, so by adding, every tensor is $1 \otimes v$ for some $v$. Now we can show $f$ has trivial kernel: if $f(t)=0$ then, writing $t=1 \otimes v$, we get $v=0$, so $t=1 \otimes 0=0$.

Example 4.22. For $V=K, K \otimes_{R} K \cong K$ as $R$-modules by $x \otimes y \mapsto x y$ on elementary tensors. For example, $\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{Q} \cong \mathbf{Q}$. If a field $K$ is inside a field $L$ then we can view $L$ as a $K$-vector space and $K \otimes_{R} L \cong L$ as $R$-modules, e.g., $\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{R} \cong \mathbf{R}$ as $\mathbf{Z}$-modules.

Theorem 4.23. Let $R$ be a domain with fraction field $K$ and $V$ be a $K$-vector space. For each nonzero $R$-module $M$ inside $K, M \otimes_{R} V \cong V$ as $R$-modules by $m \otimes v \mapsto m v$. In particular, $I \otimes_{R} K \cong K$ as $R$-modules for every nonzero ideal $I$ in $R$.
Proof. The proof is largely like that for the previous theorem. ${ }^{15}$ Multiplication gives a function $M \times V \rightarrow V$ that is $R$-bilinear, so we get an $R$-linear map $f: M \otimes_{R} V \rightarrow V$ where $f(m \otimes v)=m v$. To show $f$ is onto, we can't look at $f(1 \otimes v)$ as in the previous proof, since 1 is usually not in $M$. Instead we can just pick a nonzero $m \in M$. Then for all $v \in V$, $f(m \otimes(1 / m) v)=v$.

To show $f$ is injective, first we show all tensors in $M \otimes_{R} V$ are elementary. This sounds like our previous proof that all tensors in $K \otimes_{R} V$ are elementary, but $M$ need not be $K$, so our manipulations need to be more careful than before. (We can't write $(a / b) \otimes v$ as

[^10]$(1 / b) \otimes a v$, since $1 / b$ usually won't be in $M$.) Given a finite set of nonzero elementary tensors $m_{i} \otimes v_{i}$, each $m_{i}$ is nonzero. Write $m_{i}=a_{i} / b_{i}$ with nonzero $a_{i}$ and $b_{i}$ in $R$. Let $a \in R$ be the product of the $a_{i}$ 's and $c_{i}=a / a_{i} \in R$, so $a=a_{i} c_{i}=b_{i} c_{i} m_{i} \in M$. In $V$ we can write $v_{i}=b_{i} c_{i} w_{i}$ for some $w_{i} \in V$, so
$$
m_{i} \otimes v_{i}=m_{i} \otimes b_{i} c_{i} w_{i}=b_{i} c_{i} m_{i} \otimes w_{i}=a \otimes w_{i} .
$$

The sum of these elementary tensors is $a \otimes \sum_{i} w_{i}$, which is elementary.
Now suppose $t \in M \otimes_{R} V$ is in the kernel of $f$. All tensors in $M \otimes_{R} V$ are elementary, so we can write $t=m \otimes v$. Then $f(t)=0 \Rightarrow m v=0$ in $V$, so $m=0$ or $v=0$, and thus $t=m \otimes v=0$.
Example 4.24. Let $R=\mathbf{Z}[\sqrt{10}]$ and $K=\mathbf{Q}(\sqrt{10})$. The ideal $I=(2, \sqrt{10})$ in $R$ is not principal, so $I \not \approx R$ as $R$-modules. However, $I \otimes_{R} K \cong R \otimes_{R} K$ as $R$-modules since both are isomorphic to $K$.

Theorem 4.25. Let $R$ be a domain and $F$ and $F^{\prime}$ be free $R$-modules. If $x$ and $x^{\prime}$ are nonzero in $F$ and $F^{\prime}$, then $x \otimes x^{\prime} \neq 0$ in $F \otimes_{R} F^{\prime}$.

Proof. If we were working with vector spaces this would be trivial, since $x$ and $x^{\prime}$ are each part of a basis of $F$ and $F^{\prime}$, so $x \otimes x^{\prime}$ is part of a basis of $F \otimes_{R} F^{\prime}$ (Theorem 4.9). In a free module over a commutative ring, a nonzero element need not be part of a basis, so our proof needs to be a little more careful. We'll still uses bases, just not ones that necessarily include $x$ or $x^{\prime}$.

Pick a basis $\left\{e_{i}\right\}$ for $F$ and $\left\{e_{j}^{\prime}\right\}$ for $F^{\prime}$. Write $x=\sum_{i} a_{i} e_{i}$ and $x^{\prime}=\sum_{j} a_{j}^{\prime} e_{j}^{\prime}$. Then $x \otimes x^{\prime}=\sum_{i, j} a_{i} a_{j}^{\prime} e_{i} \otimes e_{j}^{\prime}$ in $F \otimes_{R} F^{\prime}$. Since $x$ and $x^{\prime}$ are nonzero, they each have some nonzero coefficient, say $a_{i_{0}}$ and $a_{j_{0}}^{\prime}$. Then $a_{i_{0}} a_{j_{0}}^{\prime} \neq 0$ since $R$ is a domain, so $x \otimes x^{\prime}$ has a nonzero coordinate in the basis $\left\{e_{i} \otimes e_{j}^{\prime}\right\}$ of $F \otimes_{R} F^{\prime}$. Thus $x \otimes x^{\prime} \neq 0$.
Remark 4.26. There is always a counterexample for Theorem 4.25 when $R$ is not a domain. Let $F=F^{\prime}=R$ and say $a b=0$ with $a$ and $b$ nonzero in $R$. In $R \otimes_{R} R$ we have $a \otimes b=$ $a b(1 \otimes 1)=0$.

Theorem 4.27. Let $R$ be a domain with fraction field $K$ and $V$ be a $K$-vector space.
(1) For all $R$-modules $M$, there is an $R$-module isomorphism $V \otimes_{R} M \cong V \otimes_{R}\left(M / M_{\text {tor }}\right)$, where $M_{\text {tor }}$ is the torsion submodule of $M$.
(2) For $R$-modules $M$, if $M$ is torsion then $V \otimes_{R} M=0$ and if $M$ is not torsion and $V$ is nonzero then $V \otimes_{R} M \neq 0$.
(3) If $M$ is an $R$-module and $N$ is a submodule such that $M / N$ is a torsion $R$-module then $V \otimes_{R} N \cong V \otimes_{R} M$ as $R$-modules by $v \otimes n \mapsto v \otimes n$.
Proof. (1) The map $V \times M \rightarrow V \otimes_{R}\left(M / M_{\text {tor }}\right)$ given by $(v, m) \mapsto v \otimes \bar{m}$ is $R$-bilinear, so there is an $R$-linear map $f: V \otimes_{R} M \rightarrow V \otimes_{R}\left(M / M_{\text {tor }}\right)$ where $f(v \otimes m)=v \otimes \bar{m}$.

To go the other way, the canonical $R$-bilinear map $V \times M \xrightarrow{\otimes} V \otimes_{R} M$ vanishes at ( $v, m$ ) for $m \in M_{\text {tor }}$ : if $r m=0$ for $r \neq 0$ then $v \otimes m=r(v / r) \otimes m=v / r \otimes r m=v / r \otimes 0=0$. Thus we get an induced $R$-bilinear map $V \times\left(M / M_{\text {tor }}\right) \rightarrow V \otimes_{R} M$ given by $(v, \bar{m}) \mapsto v \otimes m$. (The point is that an elementary tensor $v \otimes m$ in $V \otimes_{R} M$ only depends on $m$ through its coset $\bmod M_{\text {tor }}$.) The universal mapping property of the tensor product now gives us an $R$-linear map $g: V \otimes_{R}\left(M / M_{\text {tor }}\right) \rightarrow V \otimes_{R} M$ where $g(v \otimes \bar{m})=v \otimes m$.

The composites $g \circ f$ and $f \circ g$ are both $R$-linear and are the identity on elementary tensors, so they are the identity on all tensors and thus $f$ and $g$ are inverse isomorphisms.
(2) It is immediate from (1) that $V \otimes_{R} M=0$ if $M$ is a torsion module, since $V \otimes_{R} M \cong$ $V \otimes_{R}\left(M / M_{\text {tor }}\right)=V \otimes_{R} 0=0$. We could also prove this in a direct way, by showing all elementary tensors in $V \otimes_{R} M$ are 0 : for $v \in V$ and $m \in M$, let $r m=0$ with $r \neq 0$, so $v \otimes m=r(v / r) \otimes m=v / r \otimes r m=v / r \otimes 0=0$. Thus all tensors in $V \otimes_{R} M$ are 0 .

To show $V \otimes_{R} M \neq 0$ when $M$ is not torsion and $V \neq\{0\}$, from the isomorphism $V \otimes_{R} M \cong V \otimes_{R}\left(M / M_{\text {tor }}\right)$, we replace $M$ with $M / M_{\text {tor }}$ and are reduced to the case when $M$ is torsion-free. For torsion-free $M$ we will create a nonzero $R$-module and an $R$-linear map onto it from $V \otimes_{R} M$, so $V \otimes_{R} M \neq 0$. This will require a fair bit of work (as it usually does to prove a tensor product of $R$-modules doesn't vanish when they may not be free).

We will build an $R$-module $K M$ of formal products $x m$ with $x \in K$ and $m \in M$. To make this precise, use equivalence classes of ordered pairs in the same way that a fraction field is built out of a domain. On the product set $K \times M$, define an equivalence relation by

$$
(a / b, m) \sim(c / d, n) \Longleftrightarrow a d m=b c n \text { in } M
$$

Here $a, b, c$, and $d$ are in $R$ and $b$ and $d$ are not 0 . The proof that this relation is well-defined (independent of the choice of numerators and denominators) and transitive requires $M$ be torsion-free (check!). As an example, $(0, m) \sim(0,0)$ for all $m \in M$.

Define $K M=(K \times M) / \sim$ and write the equivalence class of $(x, m)$ as $x \cdot m$. Give $K M$ the addition and $K$-scaling formulas

$$
\frac{a}{b} \cdot m+\frac{c}{d} \cdot n=\frac{1}{b d} \cdot(a d m+b c n), \quad x(y \cdot m)=(x y) \cdot m .
$$

Check these operations on $K M$ are well-defined and make $K M$ into a $K$-vector space (so in particular an $R$-module). The function $M \rightarrow K M$ given by $m \mapsto 1 \cdot m$ is injective: if $1 \cdot m=1 \cdot m^{\prime}$ then $(1, m) \sim\left(1, m^{\prime}\right)$, so $m=m^{\prime}$ in $M$. Thus $K M \neq 0$ since $M \neq 0$.

Pick $v_{0} \neq 0$ in $V$ and extend it to a basis of $V$. Using this basis, there is a $K$-linear $\varphi: V \rightarrow K$ with $\varphi\left(v_{0}\right)=1$. The function $V \times M \rightarrow K M$ where $(v, m) \mapsto \varphi(v) \cdot m$ is $R$ bilinear and onto (since $\varphi$ is onto), so there is a surjective $R$-linear map $V \otimes_{R} M \xrightarrow{f} K M$ such that $f(v \otimes m)=\varphi(v) \cdot m$. Since $K M \neq 0$ we have $V \otimes_{R} M \neq 0$.
(3) Since $N \subset M$, there is a natural $R$-bilinear map $V \times N \rightarrow V \otimes_{R} M$, namely $(v, n) \mapsto$ $v \otimes n$. So we get automatically an $R$-linear map $f: V \otimes_{R} N \rightarrow V \otimes_{R} M$ where $f(v \otimes n)=v \otimes n$ on elementary tensors. (This is not the identity: on the left $v \otimes n$ is in $V \otimes_{R} N$ and on the right $v \otimes n$ is in $V \otimes_{R} M$.)

To get a map inverse to $f$, we can't have $V \otimes_{R} M \rightarrow V \otimes_{R} N$ by $v \otimes m \mapsto v \otimes m$, since $m$ may not be in $N$. The trick to use is that some nonzero $R$-multiple of $m$ is in $N$, since $M / N$ is a torsion module: let $V \times M \rightarrow V \otimes_{R} N$ by $(v, m) \mapsto(1 / r) v \otimes r m$ where $r m \in N$ for $r \in R-\{0\}$. (Don't try to simplify $(1 / r) v \otimes r m$ by moving $r$ through $\otimes$ from right to left, since $r m$ is in $N$ but $m$ usually is not.) We need to check $(1 / r) v \otimes r m$ is independent of the choice of $r \neq 0$ such that $r m \in N$. If $r^{\prime} m \in N$ with $r^{\prime} \in R-\{0\}$, then

$$
\frac{1}{r^{\prime}} v \otimes r^{\prime} m=\frac{r}{r r^{\prime}} v \otimes r^{\prime} m=\frac{1}{r r^{\prime}} v \otimes r r^{\prime} m=\frac{1}{r r^{\prime}} v \otimes r^{\prime}(r m)=\frac{r^{\prime}}{r r^{\prime}} v \otimes r m=\frac{1}{r} v \otimes r m .
$$

Set $V \times M \rightarrow V \otimes_{R} N$ by $(v, m) \mapsto(1 / r) v \otimes r m$ where $r \in R-\{0\}$ satisfies $r m \in N$. This is well-defined. Check it is $R$-bilinear, so we get an $R$-linear map $g: V \otimes_{R} M \rightarrow V \otimes_{R} N$ where $g(v \otimes m)=(1 / r) v \otimes r m$ for $r m \in N$ with $r \neq 0$. Check $f(g(v \otimes m))=v \otimes m$ and $g(f(v \otimes n))=v \otimes n$, so $f \circ g$ and $g \circ f$ are both the identity maps by additivity.
Corollary 4.28. With notation as in Theorem 4.27, $v \otimes m=0$ in $V \otimes_{R} M$ if and only if $v=0$ or $m \in M_{\text {tor }}$. In particular, $M_{\text {tor }}=\operatorname{ker}\left(M \rightarrow K \otimes_{R} M\right)$ where $m \mapsto 1 \otimes m$.

Proof. If $v=0$ then $v \otimes m=0 \otimes m=0$. If $m \in M_{\mathrm{tor}}$, with $r m=0$ for some nonzero $r \in R$, then $v \otimes m=(v / r) r \otimes m=(v / r) \otimes r m=(v / r) \otimes 0=0$.

Conversely, if $v \otimes m=0$ in $V \otimes_{R} M$ we will prove $v=0$ or $m \in M_{\text {tor }}$ by assuming $v \neq 0$ and showing $m \in M_{\text {tor }}$. By the natural $R$-linear map $V \otimes_{R} M \rightarrow V \otimes_{R}\left(M / M_{\text {tor }}\right)$ in the proof of Theorem 4.27(1), from $v \otimes m=0$ in $V \otimes_{R} M$ we get $v \otimes \bar{m}=0$ in $V \otimes_{R}\left(M / M_{\text {tor }}\right)$. From $v \neq 0$ and $M / M_{\text {tor }}$ being torsion-free, by the proof of Theorem $4.27(2)$ there is a $K$-linear map $\varphi: V \rightarrow K$ such that $\varphi(v)=1$ and there is an $R$-linear map $V \otimes_{R}\left(M / M_{\text {tor }}\right) \rightarrow K\left(M / M_{\text {tor }}\right)$ where $v \otimes \bar{m} \mapsto \varphi(v) \cdot \bar{m}=1 \cdot \bar{m}$, so $1 \cdot \bar{m}=0$ in $K\left(M / M_{\text {tor }}\right)$. Thus $\bar{m}=\overline{0}$ in $M / M_{\text {tor }}$ by the definition of equality in $K\left(M / M_{\text {tor }}\right)$ and its zero element being $0 \cdot \overline{0}$, so $m \in M_{\text {tor }}$.

Example 4.29. If $x \in \mathbf{R}^{\times}$and $y / \pi$ is irrational, then $x \otimes(y \bmod \pi \mathbf{Z}) \neq 0$ in $\mathbf{R} \otimes \mathbf{Z}(\mathbf{R} / \pi \mathbf{Z})$ since $(\mathbf{R} / \pi \mathbf{Z})_{\text {tor }}=\pi \mathbf{Q} / \pi \mathbf{Z}$. This is used in the modern form of Dehn's solution to Hilbert's 3rd problem, but Dehn's own solution was decades before tensor products of $\mathbf{Z}$-modules were defined. By Theorem 4.27(1), $\mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Z}) \cong \mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Z}) /(\pi \mathbf{Q} / \pi \mathbf{Z}) \cong \mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Q})$ as $\mathbf{Z}$-modules.

## 5. General Properties of Tensor Products

There are canonical isomorphisms $M \oplus N \cong N \oplus M$ and $(M \oplus N) \oplus P \cong M \oplus(N \oplus P)$. We want to show similar isomorphisms for tensor products: $M \otimes_{R} N \cong N \otimes_{R} M$ and $\left(M \otimes_{R} N\right) \otimes_{R} P \cong M \otimes_{R}\left(N \otimes_{R} P\right)$. Furthermore, there is a distributive property over direct sums: $M \otimes_{R}(N \oplus P) \cong\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$. How these modules are isomorphic is much more important than just that they are isomorphic.

Theorem 5.1. There is a unique $R$-module isomorphism $M \otimes_{R} N \cong N \otimes_{R} M$ where $m \otimes n \mapsto n \otimes m$.

Proof. We want to create a linear map $M \otimes_{R} N \rightarrow N \otimes_{R} M$ sending $m \otimes n$ to $n \otimes m$. To do this, we back up and start off with a map out of $M \times N$ to the desired target module $N \otimes_{R} M$. Define $M \times N \rightarrow N \otimes_{R} M$ by $(m, n) \mapsto n \otimes m$. This is a bilinear map since $n \otimes m$ is bilinear in $m$ and $n$. Therefore by the universal mapping property of the tensor product, there is a unique linear map $f: M \otimes_{R} N \rightarrow N \otimes_{R} M$ such that $f(m \otimes n)=n \otimes m$ on elementary tensors: the diagram

commutes.
Running through the above argument with the roles of $M$ and $N$ interchanged, there is a unique linear map $g: N \otimes_{R} M \rightarrow M \otimes_{R} N$ where $g(n \otimes m)=m \otimes n$ on elementary tensors. We will show $f$ and $g$ are inverses of each other.

To show $f(g(t))=t$ for all $t \in N \otimes_{R} M$, it suffices to check this when $t$ is an elementary tensor, since both sides are $R$-linear (or even just additive) in $t$ and $N \otimes_{R} M$ is spanned by its elementary tensors: $f(g(n \otimes m))=f(m \otimes n)=n \otimes m$. Therefore $f(g(t))=t$ for all $t \in N \otimes_{R} M$. The proof that $g(f(t))=t$ for all $t \in M \otimes_{R} N$ is similar. We have shown $f$ and $g$ are inverses of each other, so $f$ is an $R$-module isomorphism.

Theorem 5.2. There is a unique $R$-module isomorphism $\left(M \otimes_{R} N\right) \otimes_{R} P \cong M \otimes_{R}\left(N \otimes_{R} P\right)$ where $(m \otimes n) \otimes p \mapsto m \otimes(n \otimes p)$.
Proof. By Theorem 3.3, $\left(M \otimes_{R} N\right) \otimes_{R} P$ is linearly spanned by all $(m \otimes n) \otimes p$ and $M \otimes_{R}$ $\left(N \otimes_{R} P\right)$ is linearly spanned by all $m \otimes(n \otimes p)$. Therefore linear maps out of these two modules are determined by their values on these ${ }^{16}$ elementary tensors. So there is at most one linear map $\left(M \otimes_{R} N\right) \otimes_{R} P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$ with the effect $(m \otimes n) \otimes p \mapsto m \otimes(n \otimes p)$, and likewise in the other direction.

To create such a linear map $\left(M \otimes_{R} N\right) \otimes_{R} P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$, consider the function $M \times N \times P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$ given by $(m, n, p) \mapsto m \otimes(n \otimes p)$. Since $m \otimes(n \otimes p)$ is trilinear in $m$, $n$, and $p$, for each $p$ we get a bilinear map $b_{p}: M \times N \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$ where $b_{p}(m, n)=m \otimes(n \otimes p)$, which induces a linear map $f_{p}: M \otimes_{R} N \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$ such that $f_{p}(m \otimes n)=m \otimes(n \otimes p)$ on all elementary tensors $m \otimes n$ in $M \otimes_{R} N$.

Now we consider the function $\left(M \otimes_{R} N\right) \times P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$ given by $(t, p) \mapsto f_{p}(t)$. This is bilinear! First, it is linear in $t$ with $p$ fixed, since each $f_{p}$ is a linear function. Next we show it is linear in $p$ with $t$ fixed:

$$
f_{p+p^{\prime}}(t)=f_{p}(t)+f_{p^{\prime}}(t) \text { and } f_{r p}(t)=r f_{p}(t)
$$

for all $p, p^{\prime}$, and $r$. Both sides of these identities are additive in $t$, so to check them it suffices to check the case when $t=m \otimes n$ :

$$
\begin{aligned}
f_{p+p^{\prime}}(m \otimes n) & =(m \otimes n) \otimes\left(p+p^{\prime}\right) \\
& =(m \otimes n) \otimes p+(m \otimes n) \otimes p^{\prime} \\
& =f_{p}(m \otimes n)+f_{p^{\prime}}(m \otimes n) \\
& =\left(f_{p}+f_{p^{\prime}}\right)(m \otimes n) .
\end{aligned}
$$

That $f_{r p}(m \otimes n)=r f_{p}(m \otimes n)$ is left to the reader. Since $f_{p}(t)$ is bilinear in $p$ and $t$, the universal mapping property of the tensor product tells us there is a unique linear map $f:\left(M \otimes_{R} N\right) \otimes_{R} P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)$ such that $f(t \otimes p)=f_{p}(t)$. Then $f((m \otimes n) \otimes p)=$ $f_{p}(m \otimes n)=m \otimes(n \otimes p)$, so we have found a linear map with the desired values on the tensors $(m \otimes n) \otimes p$.

Similarly, there is a linear map $g: M \otimes_{R}\left(N \otimes_{R} P\right) \rightarrow\left(M \otimes_{R} N\right) \otimes_{R} P$ where $g(m \otimes(n \otimes p))=$ $(m \otimes n) \otimes p$. Easily $f(g(m \otimes(n \otimes p)))=m \otimes(n \otimes p)$ and $g(f((m \otimes n) \otimes p))=(m \otimes n) \otimes p$. Since these particular tensors linearly span the two modules, these identities extend by linearity ( $f$ and $g$ are linear) to show $f$ and $g$ are inverse functions.

Theorem 5.3. There is a unique $R$-module isomorphism

$$
M \otimes_{R}(N \oplus P) \cong\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)
$$

where $m \otimes(n, p) \mapsto(m \otimes n, m \otimes p)$.
Proof. Instead of directly writing down an isomorphism, we will put to work the essential uniqueness of solutions to a universal mapping problem by showing $\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ has the universal mapping property of the tensor product $M \otimes_{R}(N \oplus P)$. Therefore by abstract nonsense these modules must be isomorphic. That there is an isomorphism whose effect on elementary tensors in $M \otimes_{R}(N \oplus P)$ is as indicated in the statement of the theorem will fall out of our work.

[^11]For $\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ to be a tensor product of $M$ and $N \oplus P$, it needs a bilinear map to it from $M \times(N \oplus P)$. Let $b: M \times(N \oplus P) \rightarrow\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ by $b(m,(n, p))=$ $(m \otimes n, m \otimes p)$. This function is bilinear. We verify the additivity of $b$ in its second component, leaving the rest to the reader:

$$
\begin{aligned}
b\left(m,(n, p)+\left(n^{\prime}, p^{\prime}\right)\right) & =b\left(m,\left(n+n^{\prime}, p+p^{\prime}\right)\right) \\
& =\left(m \otimes\left(n+n^{\prime}\right), m \otimes\left(p+p^{\prime}\right)\right) \\
& =\left(m \otimes n+m \otimes n^{\prime}, m \otimes p+m \otimes p^{\prime}\right) \\
& =(m \otimes n, m \otimes p)+\left(m \otimes n^{\prime}, m \otimes p^{\prime}\right) \\
& =b(m,(n, p))+b\left(m,\left(n^{\prime}, p^{\prime}\right)\right) .
\end{aligned}
$$

To show $\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ and $b$ have the universal mapping property of $M \otimes_{R}(N \oplus P)$ and $\otimes$, let $B: M \times(N \oplus P) \rightarrow Q$ be a bilinear map. We seek an $R$-linear map $L$ making

commute. Being linear, $L$ would be determined by its values on the direct summands, and these values would be determined by the values of $L$ on all pairs $(m \otimes n, 0)$ and $(0, m \otimes p)$ by additivity. These values are forced by commutativity of (5.1) to be
$L(m \otimes n, 0)=L(b(m,(n, 0)))=B(m,(n, 0))$ and $L(0, m \otimes p)=L(b(m,(0, p)))=B(m,(0, p))$.
To construct $L$, the above formulas suggest the maps $M \times N \rightarrow Q$ and $M \times P \rightarrow Q$ given by $(m, n) \mapsto B(m,(n, 0))$ and $(m, p) \mapsto B(m,(0, p))$. Both are bilinear, so there are $R$-linear maps $M \otimes_{R} N \xrightarrow{L_{1}} Q$ and $M \otimes_{R} P \xrightarrow{L_{2}} Q$ where

$$
L_{1}(m \otimes n)=B(m,(n, 0)) \text { and } L_{2}(m \otimes p)=B(m,(0, p))
$$

Define $L$ on $\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ by $L\left(t_{1}, t_{2}\right)=L_{1}\left(t_{1}\right)+L_{2}\left(t_{2}\right)$. (Notice we are defining $L$ not just on ordered pairs of elementary tensors, but on all pairs of tensors. We need $L_{1}$ and $L_{2}$ to be defined on the whole tensor product modules $M \otimes_{R} N$ and $M \otimes_{R} P$.) The map $L$ is linear since $L_{1}$ and $L_{2}$ are linear, and (5.1) commutes:

$$
\begin{aligned}
L(b(m,(n, p))) & =L(b(m,(n, 0)+(0, p))) \\
& =L(b(m,(n, 0))+b(m,(0, p))) \\
& =L((m \otimes n, 0)+(0, m \otimes p)) \text { by the definition of } b \\
& =L(m \otimes n, m \otimes p) \\
& =L_{1}(m \otimes n)+L_{2}(m \otimes p) \text { by the definition of } L \\
& =B(m,(n, 0))+B(m,(0, p)) \\
& =B(m,(n, 0)+(0, p)) \\
& =B(m,(n, p)) .
\end{aligned}
$$

Now that we've shown $\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ and the bilinear map $b$ have the universal mapping property of $M \otimes_{R}(N \oplus P)$ and the canonical bilinear map $\otimes$, there is a unique
linear map $f$ making the diagram

commute, and $f$ is an isomorphism of $R$-modules because it transforms one solution of a universal mapping problem into another. Taking $(m,(n, p))$ around the diagram both ways,

$$
f(b(m,(n, p)))=f(m \otimes n, m \otimes p)=m \otimes(n, p) .
$$

Therefore the inverse of $f$ is an isomorphism $M \otimes_{R}(N \oplus P) \rightarrow\left(M \otimes_{R} N\right) \oplus\left(M \otimes_{R} P\right)$ with the effect $m \otimes(n, p) \mapsto(m \otimes n, m \otimes p)$. We look at the inverse because the theorem is saying something about an isomorphism out of $M \otimes_{R}(N \oplus P)$, which is the target of $f$.

Theorem 5.4. There is a unique $R$-module isomorphism

$$
M \otimes_{R} \bigoplus_{i \in I} N_{i} \cong \bigoplus_{i \in I}\left(M \otimes_{R} N_{i}\right)
$$

where $m \otimes\left(n_{i}\right)_{i \in I} \mapsto\left(m \otimes n_{i}\right)_{i \in I}$.
Proof. The case $I=\emptyset$ is vacuously true, so let $I \neq \emptyset$. We modify the proof when $|I|=2$ in Theorem 5.3. The map $b: M \times\left(\bigoplus_{i \in I} N_{i}\right) \rightarrow \bigoplus_{i \in I}\left(M \otimes_{R} N_{i}\right)$ by $b\left(\left(m,\left(n_{i}\right)_{i \in I}\right)\right)=\left(m \otimes n_{i}\right)_{i \in I}$ is bilinear. We will show $\bigoplus_{i \in I}\left(M \otimes_{R} N_{i}\right)$ and $b$ have the universal mapping property of $M \otimes_{R} \bigoplus_{i \in I} N_{i}$ and $\otimes$.

Let $B: M \times\left(\bigoplus_{i \in I} N_{i}\right) \rightarrow Q$ be bilinear. For each $i \in I$ the function $M \times N_{i} \rightarrow Q$ where $\left(m, n_{i}\right) \mapsto B\left(m,\left(\ldots, 0, n_{i}, 0, \ldots\right)\right)$ is bilinear, so there is a linear map $L_{i}: M \otimes_{R} N_{i} \rightarrow Q$ where $L_{i}\left(m \otimes n_{i}\right)=B\left(m,\left(\ldots, 0, n_{i}, 0, \ldots\right)\right)$. Define $L: \bigoplus_{i \in I}\left(M \otimes_{R} N_{i}\right) \rightarrow Q$ by $L\left(\left(t_{i}\right)_{i \in I}\right)=$ $\sum_{i \in I} L_{i}\left(t_{i}\right)$. All but finitely many $t_{i}$ equal 0 , so the sum here makes sense, and $L$ is linear. It is left to the reader to check the diagram

commutes. A map $L$ making this diagram commute has its value on $\left(\ldots, 0, m \otimes n_{i}, 0, \ldots\right)=$ $b\left(m,\left(\ldots, 0, n_{i}, 0, \ldots\right)\right)$ determined by $B$, so $L$ is unique. Thus $\bigoplus_{i \in I}\left(M \otimes_{R} N_{i}\right)$ and the bilinear map $b$ to it have the universal mapping property of $M \otimes_{R} \bigoplus_{i \in I} N_{i}$ and the canonical
map $\otimes$, so there is an $R$-module isomorphism $f$ making the diagram

commute. Sending $\left(m,\left(n_{i}\right)_{i \in I}\right)$ around the diagram both ways, $f\left(\left(m \otimes n_{i}\right)_{i \in I}\right)=m \otimes\left(n_{i}\right)_{i \in I}$, so the inverse of $f$ is an isomorphism with the effect $m \otimes\left(n_{i}\right)_{i \in I} \mapsto\left(m \otimes n_{i}\right)_{i \in I}$.

Remark 5.5. The analogue of Theorem 5.4 for direct products of $R$-modules has counterexamples. While there is a natural $R$-linear map

$$
\begin{equation*}
M \otimes_{R} \prod_{i \in I} N_{i} \rightarrow \prod_{i \in I}\left(M \otimes_{R} N_{i}\right) \tag{5.2}
\end{equation*}
$$

where $m \otimes\left(n_{i}\right)_{i \in I} \mapsto\left(m \otimes n_{i}\right)_{i \in I}$, it may not be an isomorphism. ${ }^{17}$ Taking $R=\mathbf{Z}, M=\mathbf{Q}$, and $N_{i}=\mathbf{Z} / p^{i} \mathbf{Z}(i \geq 1)$, the right side of (5.2) is 0 since $\mathbf{Q} \otimes_{\mathbf{Z}}\left(\mathbf{Z} / p^{i} \mathbf{Z}\right)=0$ for all $i \geq 1$ (Example 3.6). The left side of (5.2) is $\mathbf{Q} \otimes_{\mathbf{z}} \prod_{i \geq 1} \mathbf{Z} / p^{i} \mathbf{Z}$, which is not 0 by Theorem 4.27 since $\prod_{i \geq 1} \mathbf{Z} / p^{i} \mathbf{Z}$, unlike $\bigoplus_{i \in I} \mathbf{Z} / p^{i} \mathbf{Z}$, is not a torsion abelian group.

In our proof of associativity of the tensor product, we started with a function on a direct product $M \times N \times P$ and collapsed this direct product to an iterated tensor product $\left(M \otimes_{R} N\right) \otimes_{R} P$ using bilinearity twice. It is useful to record a rather general result in that direction, as a technical lemma for future convenience.

Theorem 5.6. Let $M_{1}, \ldots, M_{k}, N$ be $R$-modules, with $k>2$, and suppose

$$
M_{1} \times \cdots \times M_{k-2} \times M_{k-1} \times M_{k} \xrightarrow{\varphi} N
$$

is a function that is bilinear in $M_{k-1}$ and $M_{k}$ when other coordinates are fixed. There is a unique function

$$
M_{1} \times \cdots \times M_{k-2} \times\left(M_{k-1} \otimes_{R} M_{k}\right) \xrightarrow{\Phi} N
$$

that is linear in $M_{k-1} \otimes_{R} M_{k}$ when the other coordinates are fixed and satisfies

$$
\begin{equation*}
\Phi\left(m_{1}, \ldots, m_{k-2}, m_{k-1} \otimes m_{k}\right)=\varphi\left(m_{1}, \ldots, m_{k-2}, m_{k-1}, m_{k}\right) \tag{5.3}
\end{equation*}
$$

If $\varphi$ is multilinear in $M_{1}, \ldots, M_{k}$, then $\Phi$ is multilinear in $M_{1}, \ldots, M_{k-2}, M_{k-1} \otimes_{R} M_{k}$.
Proof. Assuming a function $\Phi$ exists satisfying (5.3) and is linear in the last coordinate when other coordinates are fixed, its value everywhere is determined by additivity in the

[^12]last coordinate: write each tensor $t \in M_{k-1} \otimes_{R} M_{k}$ in the form $t=\sum_{i=1}^{p} x_{i} \otimes y_{i}$, and then
\[

$$
\begin{aligned}
\Phi\left(m_{1}, \ldots, m_{k-2}, t\right) & =\Phi\left(m_{1}, \ldots, m_{k-2}, \sum_{i=1}^{p} x_{i} \otimes y_{i}\right) \\
& =\sum_{i=1}^{p} \Phi\left(m_{1}, \ldots, m_{k-2}, x_{i} \otimes y_{i}\right) \\
& =\sum_{i=1}^{p} \varphi\left(m_{1}, \ldots, m_{k-2}, x_{i}, y_{i}\right) .
\end{aligned}
$$
\]

It remains to show $\Phi$ exists with the desired properties.
Fix $m_{i} \in M_{i}$ for $i=1, \ldots, k-2$. Define $\varphi_{m_{1}, \ldots, m_{k-2}}: M_{k-1} \times M_{k} \rightarrow N$ by

$$
\varphi_{m_{1}, \ldots, m_{k-2}}(x, y)=\varphi\left(m_{1}, \ldots, m_{k-2}, x, y\right) .
$$

By hypothesis $\varphi_{m_{1}, \ldots, m_{k-2}}$ is bilinear in $x$ and $y$, so from the universal mapping property of the tensor product there is a linear map $\Phi_{m_{1}, \ldots, m_{k-2}}: M_{k-1} \otimes_{R} M_{k} \rightarrow N$ such that

$$
\Phi_{m_{1}, \ldots, m_{k-2}}(x \otimes y)=\varphi_{m_{1}, \ldots, m_{k-2}}(x, y)=\varphi\left(m_{1}, \ldots, m_{k-2}, x, y\right) .
$$

Define $\Phi: M_{1} \times \cdots \times M_{k-2} \times\left(M_{k-1} \otimes_{R} M_{k}\right) \rightarrow N$ by

$$
\Phi\left(m_{1}, \ldots, m_{k-2}, t\right)=\Phi_{m_{1}, \ldots, m_{k-2}}(t) .
$$

Since $\Phi_{m_{1}, \ldots, m_{k-2}}$ is a linear function on $M_{k-1} \otimes_{R} M_{k}, \Phi\left(m_{1}, \ldots, m_{k-2}, t\right)$ is linear in $t$ when $m_{1}, \ldots, m_{k-2}$ are fixed.

If $\varphi$ is multilinear in $M_{1}, \ldots, M_{k}$ we want to show $\Phi$ is multilinear in $M_{1}, \ldots, M_{k-2}$, $M_{k-1} \otimes_{R} M_{k}$. We already know $\Phi$ is linear in $M_{k-1} \otimes_{R} M_{k}$ when the other coordinates are fixed. To show $\Phi$ is linear in each of the other coordinates (fixing the rest), we carry out the computation for $M_{1}$ (the argument is similar for other $M_{i}$ 's): is

$$
\begin{aligned}
\Phi\left(x+x^{\prime}, m_{2}, \ldots, m_{k-2}, t\right) & \stackrel{?}{=} \Phi\left(x, m_{2}, \ldots, m_{k-2}, t\right)+\Phi\left(x^{\prime}, m_{2}, \ldots, m_{k-2}, t\right) \\
\Phi\left(r x, m_{2}, \ldots, m_{k-2}, t\right) & \stackrel{?}{=} r \Phi\left(x, m_{2}, \ldots, m_{k-2}, t\right)
\end{aligned}
$$

when $m_{2}, \ldots, m_{k-2}, t$ are fixed in $M_{2}, \ldots, M_{k-2}, M_{k-1} \otimes_{R} M_{k}$ ? In these two equations, both sides are additive in $t$ so it suffices to verify these two equations when $t$ is an elementary tensor $m_{k-1} \otimes m_{k}$. Then from (5.3), these two equations are true since we're assuming $\varphi$ is linear in $M_{1}$ (fixing the other coordinates).

Theorem 5.6 is not specific to functions that are bilinear in the last two coordinates: any two coordinates can be used when the function is bilinear in those two coordinates. For instance, let's revisit the proof of associativity of the tensor product in Theorem 5.2 to see why the construction of the functions $f_{p}$ in the proof of Theorem 5.3 is a special case of Theorem 5.6. Define

$$
\varphi: M \times N \times P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)
$$

by $\varphi(m, n, p)=m \otimes(n \otimes p)$. This function is trilinear, so Theorem 5.6 says we can replace $M \times N$ with its tensor product: there is a bilinear function

$$
\Phi:\left(M \otimes_{R} N\right) \times P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)
$$

such that $\Phi(m \otimes n, p)=m \otimes(n \otimes p)$. Since $\Phi$ is bilinear, there is a linear function

$$
f:\left(M \otimes_{R} N\right) \otimes_{R} P \rightarrow M \otimes_{R}\left(N \otimes_{R} P\right)
$$

such that $f(t \otimes p)=\Phi(t, p)$, so $f((m \otimes n) \otimes p)=\Phi(m \otimes n, p)=m \otimes(n \otimes p)$.
The remaining module properties we treat with the tensor product in this section involve its interaction with the Hom-module construction, so in particular the dual module construction $\left(M^{\vee}=\operatorname{Hom}_{R}(M, R)\right)$.

Theorem 5.7. For $R$-modules $M, N$, and $P$, there are $R$-module isomorphisms

$$
\operatorname{Bil}_{R}(M, N ; P) \cong \operatorname{Hom}_{R}\left(M \otimes_{R} N, P\right) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Hom}_{R}(N, P)\right)
$$

Proof. The $R$-module isomorphism from $\operatorname{Bil}_{R}(M, N ; P)$ to $\operatorname{Hom}_{R}\left(M \otimes_{R} N, P\right)$ comes from the universal mapping property of the tensor product: every bilinear map $B: M \times N \rightarrow P$ leads to a specific linear map $L_{B}: M \otimes_{R} N \rightarrow P$, and all linear maps $M \otimes_{R} N \rightarrow P$ arise in this way. The correspondence $B \mapsto L_{B}$ is an isomorphism from $\operatorname{Bil}_{N}(M, N ; P)$ to $\operatorname{Hom}_{R}\left(M \otimes_{R} N, P\right)$.

Next we explain why $\operatorname{Bil}_{R}(M, N ; P) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Hom}_{R}(N, P)\right)$, which amounts to thinking about a bilinear map $M \times N \rightarrow P$ as a family of linear maps $N \rightarrow P$ indexed by elements of $M$. If $B: M \times N \rightarrow P$ is bilinear, then for each $m \in M$ the function $B(m,-)$ is a linear map $N \rightarrow P$. Define $f_{B}: M \rightarrow \operatorname{Hom}_{R}(N, P)$ by $f_{B}(m)=B(m,-)$. (That is, $f_{B}(m)(n)=B(m, n)$.) Check $f_{B}$ is linear, partly because $B$ is linear in its first component when the second component is fixed.

Going in the other direction, if $L: M \rightarrow \operatorname{Hom}_{R}(N, P)$ is linear then for each $m \in M$ we have a linear function $L(m): N \rightarrow P$. Define $B_{L}: M \times N \rightarrow P$ to be $B_{L}(m, n)=L(m)(n)$. Check $B_{L}$ is bilinear.

It is left to the reader to check the correspondences $B \rightsquigarrow f_{B}$ and $L \rightsquigarrow B_{L}$ are each linear and are inverses of each other, $\operatorname{so} \operatorname{Bil}_{R}(M, N ; P) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Hom}_{R}(N, P)\right)$ as $R$ modules.

Here's a high-level way of interpreting the isomorphism between the second and third modules in Theorem 5.7. Write $\mathbf{F}_{N}(M)=M \otimes_{R} N$ and $\mathbf{G}_{N}(M)=\operatorname{Hom}_{R}(N, M)$, so $\mathbf{F}_{N}$ and $\mathbf{G}_{N}$ turn $R$-modules into new $R$-modules. Theorem 5.7 says

$$
\operatorname{Hom}_{R}\left(\mathbf{F}_{N}(M), P\right) \cong \operatorname{Hom}_{R}\left(M, \mathbf{G}_{N}(P)\right)
$$

This is analogous to the relation between a matrix $A$ and its transpose $A^{\top}$ inside dot products:

$$
A v \cdot w=v \cdot A^{\top} w
$$

for all vectors $v$ and $w$. So $\mathbf{F}_{N}$ and $\mathbf{G}_{N}$ are "transposes" of each other. Actually, $\mathbf{F}_{N}$ and $\mathbf{G}_{N}$ are called adjoints of each other because pairs of operators $L$ and $L^{\prime}$ in linear algebra that satisfy the relation $L v \cdot w=v \cdot L^{\prime} w$ for all vectors $v$ and $w$ are called adjoints and the relation between $\mathbf{F}_{N}$ and $\mathbf{G}_{N}$ looks similar.

Corollary 5.8. For $R$-modules $M$ and $N$, there are $R$-module isomorphisms

$$
\operatorname{Bil}_{R}(M, N ; R) \cong\left(M \otimes_{R} N\right)^{\vee} \cong \operatorname{Hom}_{R}\left(M, N^{\vee}\right) \cong \operatorname{Hom}_{R}\left(N, M^{\vee}\right)
$$

Proof. Using $P=R$ in Theorem 5.7, we get $\operatorname{Bil}_{R}(M, N ; R) \cong\left(M \otimes_{R} N\right)^{\vee} \cong \operatorname{Hom}_{R}\left(M, N^{\vee}\right)$. From $M \otimes_{R} N \cong N \otimes_{R} M$ we get $\left(M \otimes_{R} N\right)^{\vee} \cong\left(N \otimes_{R} M\right)^{\vee}$, and the second dual module is isomorphic to $\operatorname{Hom}_{R}\left(N, M^{\vee}\right)$ by Theorem 5.7 with the roles of $M$ and $N$ there reversed and $P=R$. Thus we have obtained isomorphisms between the desired modules.

The isomorphism between $\operatorname{Hom}_{R}\left(M, N^{\vee}\right)$ and $\operatorname{Hom}_{R}\left(N, M^{\vee}\right)$ amounts to viewing a map in either Hom-module as as a bilinear map $B: M \times N \rightarrow R$.

The construction of $M \otimes_{R} N$ is "symmetric" in $M$ and $N$ in the sense that $M \otimes_{R} N \cong$ $N \otimes_{R} M$ in a natural way, but Corollary 5.8 is not saying $\operatorname{Hom}_{R}(M, N) \cong \operatorname{Hom}_{R}(N, M)$ since those are not the Hom-modules in the corollary. For instance, if $R=M=\mathbf{Z}$ and $N=\mathbf{Z} / 2 \mathbf{Z}$ then $\operatorname{Hom}_{R}(M, N) \cong \mathbf{Z} / 2 \mathbf{Z}$ and $\operatorname{Hom}_{R}(N, M)=0$.
Theorem 5.9. For $R$-modules $M$ and $N$, there is a linear map $M^{\vee} \otimes_{R} N \rightarrow \operatorname{Hom}_{R}(M, N)$ sending each elementary tensor $\varphi \otimes n$ in $M^{\vee} \otimes_{R} N$ to the linear map $M \rightarrow N$ defined by $(\varphi \otimes n)(m)=\varphi(m) n$. This is an isomorphism from $M^{\vee} \otimes_{R} N$ to $\operatorname{Hom}_{R}(M, N)$ if $M$ and $N$ are finite free. In particular, if $F$ is finite free then $F^{\vee} \otimes_{R} F \cong \operatorname{End}_{R}(F)$ as $R$-modules.
Proof. We need to make an element of $M^{\vee}$ and an element of $N$ act together as a linear map $M \rightarrow N$. The function $M^{\vee} \times M \times N \rightarrow N$ given by $(\varphi, m, n) \mapsto \varphi(m) n$ is trilinear. Here the functional $\varphi \in M^{\vee}$ acts on $m$ to give a scalar, which is then multiplied by $n$. By Theorem 5.6, this trilinear map induces a bilinear map $B:\left(M^{\vee} \otimes_{R} N\right) \times M \rightarrow N$ where $B(\varphi \otimes n, m)=\varphi(m) n$. For $t \in M^{\vee} \otimes_{R} N, B(t,-)$ is in $\operatorname{Hom}_{R}(M, N)$, so we have a linear map $f: M^{\vee} \otimes_{R} N \rightarrow \operatorname{Hom}_{R}(M, N)$ by $f(t)=B(t,-)$. (Explicitly, the elementary tensor $\varphi \otimes n$ acts as a linear map $M \rightarrow N$ by the rule $(\varphi \otimes n)(m)=\varphi(m) n$.)

Now let $M$ and $N$ be finite free. To show $f$ is an isomorphism, we may suppose $M$ and $N$ are nonzero. Pick bases $\left\{e_{j}\right\}$ of $M$ and $\left\{e_{i}^{\prime}\right\}$ of $N$. (We use this indexing on the bases because the standard way to represent a linear map as a matrix from a choice of bases of $M$ and $N$ is to see where the map sends the $j$ th basis element of $M$.) Then $f$ makes $e_{j}^{\vee} \otimes e_{i}^{\prime}$ act on $M$ by sending each $e_{k}$ to $e_{j}^{\bigvee}\left(e_{k}\right) e_{i}^{\prime}=\delta_{j k} e_{i}^{\prime}$. So $f\left(e_{j}^{\vee} \otimes e_{i}^{\prime}\right) \in \operatorname{Hom}_{R}(M, N)$ sends $e_{j}$ to $e_{i}^{\prime}$ and sends every other basis element $e_{k}$ to 0 . Writing elements of $M$ and $N$ as coordinate vectors using their bases, $\operatorname{Hom}_{R}(M, N)$ becomes matrices and $f\left(e_{j}^{\vee} \otimes e_{i}^{\prime}\right)$ becomes the matrix with a 1 in the $(i, j)$ position and 0 elsewhere. Such matrices are a basis of all matrices, so the image of $f$ contains a basis of $\operatorname{Hom}_{R}(M, N)$ and thus $f$ is onto.

To show $f$ is one-to-one, suppose $f\left(\sum_{i, j} c_{i j} e_{j}^{\vee} \otimes e_{i}^{\prime}\right)=O$ in $\operatorname{Hom}_{R}(M, N)$. Applying both sides to $e_{k}$, we get $\sum_{i, j} c_{i j} \delta_{j k} e_{i}^{\prime}=0$, which says $\sum_{i} c_{i k} e_{i}^{\prime}=0$, so $c_{i k}=0$ for all $i$ and all $k$. Thus every $c_{i j}$ is 0 . This concludes the proof that $f$ is an isomorphism.

Let's work out the inverse of $f$ explicitly. For $L \in \operatorname{Hom}_{R}(M, N)$, let $L\left(e_{j}\right)=\sum_{i} a_{i j} e_{i}^{\prime}$, so $L$ has matrix representation ( $a_{i j}$ ) with respect to the chosen bases of $M$ and $N$. Write $L=f\left(\sum_{i, j} c_{i j} e_{j}^{\vee} \otimes e_{i}^{\prime}\right)$, with the coefficients $c_{i j}$ in $R$ to be determined. Then

$$
L\left(e_{k}\right)=\sum_{i, j} c_{i j}\left(e_{j}^{\vee} \otimes e_{i}^{\prime}\right)\left(e_{k}\right)=\sum_{i} c_{i k} e_{i}^{\prime},
$$

so $c_{i k}=a_{i k}$. Thus $c_{i j}=a_{i j}$ for all $i$ and $j$, so the $L \in \operatorname{Hom}_{R}(M, N)$ with matrix representation ( $a_{i j}$ ) corresponds to the tensor $\sum_{i, j} a_{i j} e_{j}^{\vee} \otimes e_{i}^{\prime}$ in $M^{\vee} \otimes_{R} N$.

It looks strange to use tensors indexed as $e_{j}^{\vee} \otimes e_{i}^{\prime}$, so rewrite the isomorphism $M^{\vee} \otimes_{R} N \rightarrow$ $\operatorname{Hom}_{R}(M, N)$ as $N \otimes_{R} M^{\vee} \rightarrow \operatorname{Hom}_{R}(M, N)$ with $(n \otimes \varphi)(m)=\varphi(m) n$. Then $\sum_{i, j} a_{i j} e_{i}^{\prime} \otimes e_{j}^{\vee}$ in $N \otimes_{R} M^{\vee}$ corresponds to the linear map $M \rightarrow N$ with matrix representation ( $a_{i j}$ ) for the chosen bases of $M$ and $N$.
Remark 5.10. If $M$ and $N$ are not both finite free, the map $M^{\vee} \otimes_{R} N \rightarrow \operatorname{Hom}_{R}(M, N)$ in Theorem 5.9 may not be an isomorphism, or even injective or surjective. For example, let $p$ be prime, $R=\mathbf{Z} / p^{2} \mathbf{Z}$, and $M=N=R / p R$ as $R$-modules. Check that $M^{\vee} \cong M$, $M \otimes_{R} M \cong M$, and $\operatorname{Hom}_{R}(M, M) \cong M$, but the map $M^{\vee} \otimes_{R} M \rightarrow \operatorname{Hom}_{R}(M, M)$ in Theorem 5.9 is identically 0 (it suffices to show each elementary tensor in $M^{\vee} \otimes_{R} M$ acts on $M$ as 0 ). Notice $M^{\vee} \otimes_{R} M$ and $\operatorname{Hom}_{R}(M, M)$ are isomorphic, but the natural linear map between them happens to be identically 0 .

Example 5.11. Finite-dimensional $K$-vector spaces $V$ and $W$ have finite bases, so Theorem 5.9 says $V^{\vee} \otimes_{K} W \cong \operatorname{Hom}_{K}(V, W)$ by sending each elementary tensor $\varphi \otimes w$ to the linear map $V \rightarrow W$ given by the rule $(\varphi \otimes w)(v)=\varphi(v) w$ for all $v \in V$ and $W \otimes_{K} V^{\vee} \cong \operatorname{Hom}_{K}(V, W)$ by sending each elementary tensor $w \otimes \varphi$ to the linear map $V \rightarrow W$ where $(w \otimes \varphi)(v)=\varphi(v) w$ for all $v \in V$. This is one of the most basic ways tensor products occur in linear algebra.

What is the isomorphism $W \otimes_{K} V^{\vee} \rightarrow \operatorname{Hom}_{K}(V, W)$ really saying? For each $w \in W$ and $\varphi \in V^{\vee}$, we get a linear map $V \rightarrow W$ by $v \mapsto \varphi(v) w$, whose image as $v$ varies is the scalar multiples of $w$ (unless $\varphi=0$ ). Since the expression $\varphi(v) w$ is bilinear in $\varphi$ and $w$, we can regard the linear map $V \rightarrow W$ where $v \mapsto \varphi(v) w$ as defining an effect of $w \otimes \varphi$ on $V$, with values in $W$, and all linear maps $V \rightarrow W$ are sums of such maps. This corresponds to the fact that every matrix is a sum of matrices with at most one nonzero entry.

For instance, when $V=W=K^{2}$ with basis $e_{1}=\binom{1}{0}$ and $e_{2}=\binom{0}{1}$, let $\varphi \in K^{2}$ by $\varphi\binom{x}{y}=x$. Then $\left(e_{2} \otimes \varphi\right)\binom{x}{y}=x e_{2}=\binom{0}{x}$, so $e_{2} \otimes \varphi=\left(\begin{array}{cc}0 & 0 \\ 1 & 0\end{array}\right)$ as a linear map $K^{2} \rightarrow K^{2}$.

By the last paragraph of the proof of Theorem 5.9, the isomorphism $W \otimes_{K} V^{\vee} \rightarrow$ $\operatorname{Hom}_{K}(V, W)$ can be described in terms of bases $\left\{e_{i}^{\prime}\right\}$ of $W$ and $\left\{e_{j}\right\}$ of $V$ by sending the tensor $\sum_{i, j} a_{i j} e_{i}^{\prime} \otimes e_{j}^{\vee}$ to the linear map $L \in \operatorname{Hom}_{K}(V, W)$ where $L\left(e_{j}\right)=\sum_{i} a_{i j} e_{i}^{\prime}$.

When $M$ and $N$ are finite free $R$-modules, the isomorphisms in Corollary 5.8 and Theorem 5.9 lead to a basis-free description of $M \otimes_{R} N$ making no mention of universal mapping properties. Identify $M$ with $M^{\vee \vee}$ by double duality, so Theorem 5.9 with $M^{\vee}$ in place of $M$ assumes the form

$$
M \otimes_{R} N \cong \operatorname{Hom}_{R}\left(M^{\vee}, N\right)
$$

where $m \otimes n$ acts as a linear map $M^{\vee} \rightarrow N$ by the rule $(m \otimes n)(\varphi)=\varphi(m) n$. Since $N \cong N^{\vee \vee}$ by double duality, $\operatorname{Hom}_{R}\left(M^{\vee}, N\right) \cong \operatorname{Hom}_{R}\left(M^{\vee},\left(N^{\vee}\right)^{\vee}\right) \cong \operatorname{Bil}_{R}\left(M^{\vee}, N^{\vee} ; R\right)$ by Corollary 5.8. Therefore

$$
\begin{equation*}
M \otimes_{R} N \cong \operatorname{Bil}_{R}\left(M^{\vee}, N^{\vee} ; R\right), \tag{5.4}
\end{equation*}
$$

where $m \otimes n$ acts as a bilinear map $M^{\vee} \times N^{\vee} \rightarrow R$ by the rule $(m \otimes n)(\varphi, \psi)=\varphi(m) \psi(n)$. Similarly, $M^{\otimes k}$ is isomorphic to the module of $k$-multilinear maps $\left(M^{\vee}\right)^{k} \rightarrow R$, with the elementary tensor $m_{1} \otimes \cdots \otimes m_{k}$ defining the map sending $\left(\varphi_{1}, \ldots, \varphi_{k}\right)$ to $\varphi_{1}\left(m_{1}\right) \cdots \varphi_{k}\left(m_{k}\right)$.

The definition of the tensor product of finite-dimensional vector spaces in [1, p. 65] and [18, p. 35] is essentially (5.4). ${ }^{18}$ It is a good exercise to check these interpretations of $m \otimes n$ as a member of $\operatorname{Hom}_{R}\left(M^{\vee}, N\right)$ and $\operatorname{Bil}_{R}\left(M^{\vee}, N^{\vee} ; R\right)$ are identified with each other by Corollary 5.8 and double duality.

Watch out! The isomorphism (5.4) is false for general modules $M$ and $N$ (where double duality doesn't hold). There is always a linear map $M \otimes_{R} N \rightarrow \operatorname{Bil}_{R}\left(M^{\vee}, N^{\vee} ; R\right)$ given on elementary tensors by $m \otimes n \mapsto[(\varphi, \psi) \mapsto \varphi(m) \psi(n)]$, but it need not be an isomorphism.

Example 5.12. Let $p$ be prime, $R=\mathbf{Z} / p^{2} \mathbf{Z}$, and $M=R / p R$. The $R$-modules $M \otimes_{R} M$ and $\operatorname{Bil}_{R}\left(M^{\vee}, M^{\vee} ; R\right)$ are isomorphic to each other (and to $M$ ), but the natural map $M \otimes_{R} M \rightarrow$ $\operatorname{Bil}_{R}\left(M^{\vee}, M^{\vee} ; R\right)$ is identically 0 .

Example 5.13. Let $R=\mathbf{Z}$ and $M=N=\mathbf{Q}$. Since $\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{Q} \cong \mathbf{Q}$ as $\mathbf{Z}$-modules (Example $4.22)$ and $\mathbf{Q}^{\vee}=\operatorname{Hom}_{\mathbf{Z}}(\mathbf{Q}, \mathbf{Z})=0$, the left side of (5.4) is nonzero and the right side is 0 .

[^13]For finite-dimensional $K$-vector spaces $V$ and $W$, the rank of a linear map $L: V \rightarrow W$ is the dimension of the image $L(V)$. This is one of the most important numerical invariants of $L$ (e.g., the rank-nullity theorem). It has an interesting interpretation when $L$ is viewed as a tensor in $V^{\vee} \otimes_{K} W$ (or $W \otimes_{K} V^{\vee}$ ) by the isomorphism in Example 5.11, as follows.
Theorem 5.14. With notation as above, the rank of $L: V \rightarrow W$ is the smallest $d \geq 0$ such that $L$ is a sum of d nonzero elementary tensors when $L$ is viewed in $V^{\vee} \otimes_{K} W$.
Proof. The result is trivial when $L=O$ (rank is 0 ), so we can assume $L \neq O$ (positive rank). Let $r \geq 1$ be the rank of $L$. We will show (i) if $L$ is a sum of $d$ elementary tensors then $r \leq d$ and (ii) $L$ is a sum of $r$ (nonzero) elementary tensors.

Suppose $L=\varphi_{1} \otimes w_{1}+\cdots+\varphi_{d} \otimes w_{d}$. Then for each $v \in V, L(v)=\sum_{i=1}^{d} \varphi_{i}(v) w_{i}$, which is in the span of $w_{1}, \ldots, w_{d}$. Thus $L(V) \subset \operatorname{Span}\left(w_{1}, \ldots, w_{d}\right)$, so $r=\operatorname{dim}_{K} L(V) \leq d$.

To prove $L$ is a sum of $r$ elementary tensors in $V^{\vee} \otimes_{K} W$, let $L(V)$ have basis $\left\{e_{1}, \ldots, e_{r}\right\}$. For $v \in V$, write $L(v)$ as a linear combination of the $e_{i}$ 's: $L(v)=c_{1} e_{1}+\cdots+c_{r} e_{r}$ where $c_{1}, \ldots, c_{r} \in K$. These coefficients are uniquely determined for each $v$ because $e_{1}, \ldots, e_{r}$ are linearly independent. ${ }^{19}$ Therefore each coefficient is a function of $v$. Writing $c_{i}=c_{i}(v)$,

$$
\begin{equation*}
L(v)=c_{1}(v) e_{1}+\cdots+c_{r}(v) e_{r} \tag{5.5}
\end{equation*}
$$

Since $L$ is $K$-linear, the coefficient functions $c_{i}: V \rightarrow K$ are each $K$-linear. For example, if $v$ and $v^{\prime}$ are in $V$ then

$$
L(v)+L\left(v^{\prime}\right)=\left(c_{1}(v) e_{1}+\cdots+c_{r}(v) e_{r}\right)+\left(c_{1}\left(v^{\prime}\right) e_{1}+\cdots+c_{r}\left(v^{\prime}\right) e_{r}\right)=\sum_{i=1}^{r}\left(c_{i}(v)+c_{i}\left(v^{\prime}\right)\right) e_{i}
$$

and

$$
L\left(v+v^{\prime}\right)=\sum_{i=1}^{r} c_{i}\left(v+v^{\prime}\right) e_{i},
$$

so the equation $L\left(v+v^{\prime}\right)=L(v)+L\left(v^{\prime}\right)$ and the linear independence of the $e_{i}$ 's implies $c_{i}\left(v+v^{\prime}\right)=c_{i}(v)+c_{i}\left(v^{\prime}\right)$ for all $i$ and all $v$ and $v^{\prime}$. Thus each $c_{i}$ is additive. In a similar way, $c_{i}(a v)=a c_{i}(v)$ for all $a \in K$ and $v \in V$, so each $c_{i}$ is linear.

Because $c_{i}$ is a linear map from $V$ to $K$ it is in the dual space $V^{\vee}$. Then (5.5) as an identity for all $v$ is another way of saying $L=c_{1} \otimes e_{1}+\cdots+c_{r} \otimes e_{r}$ in $V^{\vee} \otimes_{K} W$, so $L$ is a sum of $r$ elementary tensors. These elementary tensors are all nonzero since we already showed $L$ can't be a sum of fewer than $r$ elementary tensors in $V^{\vee} \otimes_{K} W .{ }^{20}$

Inspired by Theorem 5.14, define the rank of a tensor $t$ in $M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}$ to be the smallest number of nonzero elementary tensors that sum to $t$ (the rank of the zero tensor is $0)$. For finite-dimensional vector spaces $V$ and $W$, a tensor's rank in $V \otimes_{K} W$ can be found by viewing $V$ or $W$ as a dual space so tensors in $V \otimes_{K} W$ become linear maps.

Example 5.15. In $\mathbf{R}^{3} \otimes_{\mathbf{R}} \mathbf{R}^{4}$ here is a sum of 12 elementary tensors built from the standard bases $e_{1}, e_{2}, e_{3}$ of $\mathbf{R}^{3}$ and $e_{1}^{\prime}, e_{2}^{\prime}, e_{3}^{\prime}, e_{4}^{\prime}$ of $\mathbf{R}^{4}$ :

$$
\begin{align*}
t= & e_{1} \otimes e_{1}^{\prime}+4 e_{1} \otimes e_{2}^{\prime}+2 e_{1} \otimes e_{3}^{\prime}+3 e_{1} \otimes e_{4}^{\prime}+2 e_{2} \otimes e_{1}^{\prime}+5 e_{2} \otimes e_{2}^{\prime}+  \tag{5.6}\\
& 3 e_{2} \otimes e_{3}^{\prime}+4 e_{2} \otimes e_{4}^{\prime}+e_{3} \otimes e_{1}^{\prime}+7 e_{3} \otimes e_{2}^{\prime}+3 e_{3} \otimes e_{3}^{\prime}+5 e_{3} \otimes e_{4}^{\prime}
\end{align*}
$$

[^14]To find the rank of $t$, we convert $t$ into a linear map $\mathbf{R}^{3} \rightarrow \mathbf{R}^{4}$ by identifying $\mathbf{R}^{3}$ with its dual space so that $\mathbf{R}^{3} \otimes_{\mathbf{R}} \mathbf{R}^{4} \cong\left(\mathbf{R}^{3}\right)^{\vee} \otimes_{\mathbf{R}} \mathbf{R}^{4} \cong \operatorname{Hom}_{\mathbf{R}}\left(\mathbf{R}^{3}, \mathbf{R}^{4}\right)$ and the Hom-space is thought of as $4 \times 3$ matrices. View $\mathbf{R}^{3}$ (and $\left.\mathbf{R}^{4}\right)$ as column vectors and $\left(\mathbf{R}^{3}\right)^{\vee}$ as row vectors that act on column vectors by multiplication from the left. Then for $\mathbf{v} \in \mathbf{R}^{3}$ and $\mathbf{w} \in \mathbf{R}^{4}$, $\mathbf{v} \otimes \mathbf{w}: \mathbf{R}^{3} \rightarrow \mathbf{R}^{4}$ by $\mathbf{x} \mapsto \mathbf{w}\left(\mathbf{v}^{\top} \mathbf{x}\right)=\left(\mathbf{w}^{\top}\right) \mathbf{x}$. Since $e_{i}^{\prime} e_{j}^{\top}$ has 1 in the $(i, j)$ component and 0 elsewhere, the tensor $t$ above corresponds under $\mathbf{R}^{3} \otimes_{\mathbf{R}} \mathbf{R}^{4} \cong \operatorname{Hom}\left(\mathbf{R}^{3}, \mathbf{R}^{4}\right)$ to the matrix

$$
A=\left(\begin{array}{lll}
1 & 2 & 1 \\
4 & 5 & 7 \\
2 & 3 & 3 \\
3 & 4 & 5
\end{array}\right)
$$

Let the columns of $A$ be $\mathbf{w}_{1}, \mathbf{w}_{2}$, and $\mathbf{w}_{3}$. The row reduced form of $A$ is

$$
\left(\begin{array}{rrr}
1 & 0 & 3 \\
0 & 1 & -1 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right)
$$

which tells us $\mathbf{w}_{1}$ and $\mathbf{w}_{2}$ are linearly independent and $\mathbf{w}_{3}=3 \mathbf{w}_{1}-\mathbf{w}_{2}$. Thus $A$ has rank 2 , so $t$ has rank 2: it is a sum of two elementary tensors. What could those two tensors be?!?

To find two elementary tensors with sum $t$, we use the proof of Theorem 5.14. Let $c_{1}, c_{2}: \mathbf{R}^{3} \rightarrow \mathbf{R}$ be coefficient functions for $A(\mathbf{v})=c_{1}(\mathbf{v}) \mathbf{w}_{1}+c_{2}(\mathbf{v}) \mathbf{w}_{2}$ as $\mathbf{v}$ runs over $\mathbf{R}^{3}$. Using the basis vectors $e_{1}, e_{2}, e_{3}$ of $\mathbf{R}^{3}$ in the role of $\mathbf{v}$, we have

$$
A\left(e_{1}\right)=\mathbf{w}_{1}, \quad A\left(e_{2}\right)=\mathbf{w}_{2}, \quad A\left(e_{3}\right)=3 \mathbf{w}_{1}-\mathbf{w}_{2}
$$

so $c_{1}=e_{1}^{\vee}+3 e_{3}^{\vee}=\left(e_{1}+3 e_{3}\right)^{\vee}$ and $c_{2}=e_{2}^{\vee}-e_{3}^{\vee}=\left(e_{2}-e_{3}\right)^{\vee}$. Thus in $\mathbf{R}^{3} \otimes_{\mathbf{R}} \mathbf{R}^{4}$,

$$
t=\left(e_{1}+3 e_{3}\right) \otimes \mathbf{w}_{1}+\left(e_{2}-e_{3}\right) \otimes \mathbf{w}_{2}
$$

which is a sum of two elementary tensors. In more explicit form,

$$
\begin{equation*}
t=\left(e_{1}+3 e_{3}\right) \otimes\left(e_{1}^{\prime}+4 e_{2}^{\prime}+2 e_{3}^{\prime}+3 e_{4}^{\prime}\right)+\left(e_{2}-e_{3}\right) \otimes\left(2 e_{1}^{\prime}+5 e_{2}^{\prime}+3 e_{3}^{\prime}+4 e_{4}^{\prime}\right) \tag{5.7}
\end{equation*}
$$

You can expand the right side of (5.7) to check you get (5.6), or in terms of matrices check

$$
A=\mathbf{w}_{1}\left(e_{1}+3 e_{3}\right)^{\top}+\mathbf{w}_{2}\left(e_{2}-e_{3}\right)^{\top}=\left(\begin{array}{l}
1 \\
4 \\
2 \\
3
\end{array}\right)\left(\begin{array}{lll}
1 & 0 & 3
\end{array}\right)+\left(\begin{array}{l}
2 \\
5 \\
3 \\
4
\end{array}\right)\left(\begin{array}{lll}
0 & 1 & -1
\end{array}\right) .
$$

Example 5.16. If $V$ is an $n$-dimensional vector space over $K$ with a basis $e_{1}, \ldots, e_{n}$, then $\sum_{i=1}^{n} e_{i} \otimes e_{i}$ has tensor rank $n$ : it is not a sum of fewer than $n$ elementary tensors in $V \otimes_{K} V$.

To see why, use the isomorphism $V \otimes_{K} V \rightarrow \operatorname{Hom}_{K}(V, V)$ where $v \otimes v^{\prime} \mapsto\left[w \mapsto(v \cdot w) v^{\prime}\right]$ on elementary tensors, with $v \cdot w$ being the dot product with respect to the chosen basis of $V$ : for $v=\sum_{i=1}^{n} a_{i} e_{i}$ and $w=\sum_{j=1}^{n} b_{i} e_{i}, v \cdot w:=\sum_{i=1}^{n} a_{i} b_{i}$. Then $e_{i} \cdot w=b_{i}$ and $w=\sum_{i=1}^{n}\left(e_{i} \cdot w\right) e_{i}$, so $e_{i} \otimes e_{i} \mapsto\left[w \mapsto\left(e_{i} \cdot w\right) e_{i}=b_{i} e_{i}\right]$ and $\sum_{i=1}^{n} e_{i} \otimes e_{i} \mapsto\left[w \mapsto \sum_{i=1}^{n}\left(e_{i} \cdot w\right) e_{i}=w\right]$. That means $\sum_{i=1}^{n} e_{i} \otimes e_{i}$ in $V \otimes_{K} V$ corresponds to the identity map in $\operatorname{Hom}_{K}(V, V)$. The image of the identity map on $V$ has dimension $n$, so $\sum_{i=1}^{n} e_{i} \otimes e_{i}$ in $V \otimes_{K} V$ has tensor rank $n$.

The rank of a linear map from an $m$-dimensional vector space to an $n$-dimensional vector space is at most $\min (m, n)$ and this minimum is easy to achieve: use an injective map if $m \leq n$ and a surjective map if $m \geq n$. Therefore the maximal rank among all tensors in $V \otimes_{K} W$ is $\min \left(\operatorname{dim}_{K} V, \operatorname{dim}_{K} W\right)$. For example, if $\operatorname{dim}_{K} V=n$ then every basis of $V \otimes_{K} V$
consists of $n^{2}$ tensors but each element of $V \otimes_{K} V$ is a sum of at most $n$ elementary tensors (which of course might not be linearly independent).

Computing the maximal rank among all tensors in a tensor product of three vector spaces is hard in general. Håstad [11] showed it is an NP-complete problem for vector spaces over finite fields and an NP-hard problem for vector spaces over $\mathbf{Q}$. If $n \geq 3$, the maximal tensor rank in the 3 -fold tensor product $\left(\mathbf{C}^{n}\right)^{\otimes 3}$ is known for $n=3$ (it's 5) and is unknown for $n \geq 4$ (upper bounds are known, but not the exact maximum). ${ }^{21}$ In a tensor product of three free modules over an integral domain, Shitov [23] showed computing tensor rank in general is NP-hard and over $\mathbf{Z}$ in particular it is undecidable. To quote the title of [12], "most tensor problems are NP-hard".

As an application of tensor rank, we can settle an issue that was mentioned in Remark 4.17: give an example of a linear map $M \otimes_{R} N \rightarrow P$ for some $R, M, N$, and $P$ such that the map is not injective on $M \otimes_{R} N$ and is injective on the elementary tensors in $M \otimes_{R} N$. The example below and the method leading up to it was pointed out to me by Darij Grinberg.

We begin with a necessary and sufficient condition to be injective on the elementary tensors, in terms of tensor rank.

Theorem 5.17. A linear map $f: M \otimes_{R} N \rightarrow P$ is injective on the elementary tensors in $M \otimes_{R} N$ if and only if the only element of $\operatorname{ker} f$ with tensor rank at most 2 is 0 .

Proof. First suppose $f$ is injective on the elementary tensors. If $f(t)=0$ and $t$ has tensor rank at most 2, then $t$ can be written as $m \otimes n-m^{\prime} \otimes n^{\prime}$ (if $t$ has tensor rank at most 1 , we can use $\left.m^{\prime}=0\right)$. Then $0=f(t)=f(m \otimes n)-f\left(m^{\prime} \otimes n^{\prime}\right)$, so $f(m \otimes n)=f\left(m^{\prime} \otimes n^{\prime}\right)$. Since $f$ is injective on elementary tensors, $m \otimes n=m^{\prime} \otimes n^{\prime}$, so $t=m \otimes n-m^{\prime} \otimes n^{\prime}=0$.

Conversely, suppose the only element of $\operatorname{ker} f$ with tensor rank at most 2 is 0 . If two elementary tensors $m \otimes n$ and $m^{\prime} \otimes n^{\prime}$ satisfy $f(m \otimes n)=f\left(m^{\prime} \otimes n^{\prime}\right)$, then $f\left(m \otimes n-m^{\prime} \otimes n^{\prime}\right)=$ 0 , so $m \otimes n-m^{\prime} \otimes n^{\prime}$ is in $\operatorname{ker} f$ and has tensor rank at most 2 , so this tensor is 0 , which implies $m \otimes n=m^{\prime} \otimes n^{\prime}$.

Corollary 5.18. A linear map $f: M \otimes_{R} N \rightarrow P$ is not injective on $M \otimes_{R} N$ and is injective on the elementary tensors in $M \otimes_{R} N$ if and only if $\operatorname{ker} f$ is nonzero and each nonzero element of $\operatorname{ker} f$ has tensor rank at least 3 .

Proof. Saying $f$ is not injective on $M \otimes_{R} N$ is equivalent to ker $f$ being nonzero, and saying $f$ is injective on the elementary tensors of $M \otimes_{R} N$ is equivalent to ker $f$ having no element with tensor rank below 3 other than 0 .

Example 5.19. Let $V$ be a vector space over a field $K$ with dimension $n \geq 3$. In $V \otimes_{K} V$, the tensor $t=\sum_{i=1}^{n} e_{i} \otimes e_{i}$ has rank $n$ (Example 5.16), so the natural reduction map $f: V \otimes_{K} V \rightarrow\left(V \otimes_{K} V\right) / K t$ is linear with nonzero kernel $K t$. The nonzero elements of $K t$ have tensor rank $n \geq 3$, so $f$ is injective on elementary tensors in $V \otimes_{K} V$ but not injective on $V \otimes_{K} V$ by Corollary 5.18.

When $\operatorname{dim}_{K} V=2$, there is nothing like Example 5.19: a linear map $V \otimes_{K} V \rightarrow W$ (arbitrary target space $W$ ) that's injective on the elementary tensors has to be injective on $V \otimes_{K} V$ because every element of $V \otimes_{K} V$ has tensor rank at most $\operatorname{dim}_{K} V=2$, so the criterion in Corollary 5.18 cannot be satisfied.

[^15]
## 6. Base Extension

In algebra, there are many times a module over one ring is replaced by a related module over another ring. For instance, in linear algebra it is useful to enlarge $\mathbf{R}^{n}$ to $\mathbf{C}^{n}$, creating in this way a complex vector space by letting the real coordinates be extended to complex coordinates. In ring theory, irreducibility tests in $\mathbf{Z}[X]$ involve viewing a polynomial in $\mathbf{Z}[X]$ as a polynomial in $\mathbf{Q}[X]$ or reducing the coefficients $\bmod p$ to view it in $(\mathbf{Z} / p \mathbf{Z})[X]$. We will see that all these passages to modules with new coefficients ( $\mathbf{R}^{n} \rightsquigarrow \mathbf{C}^{n}, \mathbf{Z}[X] \rightsquigarrow$ $\mathbf{Q}[X], \mathbf{Z}[X] \rightsquigarrow(\mathbf{Z} / p \mathbf{Z})[X])$ can be described in a uniform way using tensor products.

Let $f: R \rightarrow S$ be a homomorphism of commutative rings. We use $f$ to consider a $S$ module $N$ as an $R$-module by $r n:=f(r) n$. In particular, $S$ itself is an $R$-module by $r s:=f(r) s$. Passing from $N$ as an $S$-module to $N$ as an $R$-module in this way is called restriction of scalars.

Example 6.1. If $R \subset S, f$ can be the inclusion map (e.g., $\mathbf{R} \hookrightarrow \mathbf{C}$ or $\mathbf{Q} \hookrightarrow \mathbf{C}$ ). This is how a $\mathbf{C}$-vector space is thought of as an $\mathbf{R}$-vector space or a $\mathbf{Q}$-vector space.

Example 6.2. If $S=R / I, f$ can be reduction modulo $I$ : each $R / I$-module is also an $R$-module by letting $r$ act in the way that $r \bmod I$ acts.

Here is a simple illustration of restriction of scalars.
Theorem 6.3. Let $N$ and $N^{\prime}$ be $S$-modules. An $S$-linear map $N \rightarrow N^{\prime}$ is also an $R$-linear map when we treat $N$ and $N^{\prime}$ as $R$-modules.

Proof. Let $\varphi: N \rightarrow N^{\prime}$ be $S$-linear, so $\varphi(s n)=s \varphi(n)$ for all $s \in S$ and $n \in N$. For $r \in R$,

$$
\varphi(r n)=\varphi(f(r) n)=f(r) \varphi(n)=r \varphi(n),
$$

so $\varphi$ is $R$-linear.
As a notational convention, since we will be going back and forth between $R$-modules and $S$-modules a lot, we will write $M$ (or $M^{\prime}$, and so on) for $R$-modules and $N$ (or $N^{\prime}$, and so on) for $S$-modules. Since $N$ is also an $R$-module by restriction of scalars, we can form the tensor product $R$-module $M \otimes_{R} N$, where

$$
r(m \otimes n)=(r m) \otimes n=m \otimes r n
$$

with the third expression really being $m \otimes f(r) n$ since $r n:=f(r) n$.
The idea of base extension is to reverse the process of restriction of scalars. For an $R$ module $M$ we want to create an $S$-module of products $s m$ that matches the old meaning of $r m$ if $s=f(r)$. This new $S$-module is called an extension of scalars or base extension. It will be the $R$-module $S \otimes_{R} M$ equipped with a specific structure of an $S$-module.

Since $S$ is a ring, not just an $R$-module, let's try making $S \otimes_{R} M$ into an $S$-module by

$$
\begin{equation*}
s^{\prime}(s \otimes m):=s^{\prime} s \otimes m . \tag{6.1}
\end{equation*}
$$

Is this $S$-scaling on elementary tensors well-defined and does it extend to $S$-scaling on all tensors?

Theorem 6.4. The additive group $S \otimes_{R} M$ has a unique $S$-module structure satisfying (6.1), and this is compatible with the $R$-module structure in the sense that $r t=f(r) t$ for all $r \in R$ and $t \in S \otimes_{R} M$.

Proof. Suppose the additive group $S \otimes_{R} M$ has an $S$-module structure satisfying (6.1). We will show the $S$-scaling on all tensors in $S \otimes_{R} M$ is determined by this. Each $t \in S \otimes_{R} M$ is a finite sum of elementary tensors, say

$$
t=s_{1} \otimes m_{1}+\cdots+s_{k} \otimes m_{k} .
$$

For $s \in S$,

$$
\begin{aligned}
s t & =s\left(s_{1} \otimes m_{1}+\cdots+s_{k} \otimes m_{k}\right) \\
& =s\left(s_{1} \otimes m_{1}\right)+\cdots+s\left(s_{k} \otimes m_{k}\right) \\
& =s s_{1} \otimes m_{1}+\cdots+s s_{k} \otimes m_{k} \quad \text { by }(6.1),
\end{aligned}
$$

so $s t$ is determined, although this formula for it is not obviously well-defined. (Does a different expression for $t$ as a sum of elementary tensors change $s t$ ?)

Now we show there really is an $S$-module structure on $S \otimes_{R} M$ satisfying (6.1). Describing the $S$-scaling on $S \otimes_{R} M$ means creating a function $S \times\left(S \otimes_{R} M\right) \rightarrow S \otimes_{R} M$ satisfying the relevant scaling axioms:

$$
\begin{equation*}
1 \cdot t=t, \quad s\left(t_{1}+t_{2}\right)=s t_{1}+s t_{2}, \quad\left(s_{1}+s_{2}\right) t=s_{1} t+s_{2} t, \quad s_{1}\left(s_{2} t\right)=\left(s_{1} s_{2}\right) t . \tag{6.2}
\end{equation*}
$$

For each $s^{\prime} \in S$ we consider the function $S \times M \rightarrow S \otimes_{R} M$ given by $(s, m) \mapsto\left(s^{\prime} s\right) \otimes m$. This is $R$-bilinear, so by the universal mapping property of tensor products there is an $R$-linear map $\mu_{s^{\prime}}: S \otimes_{R} M \rightarrow S \otimes_{R} M$ where $\mu_{s^{\prime}}(s \otimes m)=\left(s^{\prime} s\right) \otimes m$ on elementary tensors. Define a multiplication $S \times\left(S \otimes_{R} M\right) \rightarrow S \otimes_{R} M$ by $s^{\prime} t:=\mu_{s^{\prime}}(t)$. This will be the scaling of $S$ on $S \otimes_{R} M$. We check the conditions in (6.2):
(1) To show $1 t=t$ means showing $\mu_{1}(t)=t$. On elementary tensors, $\mu_{1}(s \otimes m)=$ $(1 \cdot s) \otimes m=s \otimes m$, so $\mu_{1}$ fixes elementary tensors. Therefore $\mu_{1}$ fixes all tensors by additivity.
(2) $s\left(t_{1}+t_{2}\right)=s t_{1}+s t_{2}$ since $\mu_{s}$ is additive.
(3) Showing $\left(s_{1}+s_{2}\right) t=s_{1} t+s_{2} t$ means showing $\mu_{s_{1}+s_{2}}=\mu_{s_{1}}+\mu_{s_{2}}$ as functions on $S \otimes_{R} M$. Both sides are additive functions, so it suffices to check they agree on elementary tensors $s \otimes m$, where both sides have common value $\left(s_{1}+s_{2}\right) s \otimes m$.
(4) To show $s_{1}\left(s_{2} t\right)=\left(s_{1} s_{2}\right) t$ means $\mu_{s_{1}} \circ \mu_{s_{2}}=\mu_{s_{1} s_{2}}$ as functions on $S \otimes_{R} M$. Both sides are additive functions of $t$, so it suffices to check they agree on elementary tensors $s \otimes m$, where both sides have common value $\left(s_{1} s_{2} s\right) \otimes m$.
Let's check the $S$-module structure on $S \otimes_{R} M$ is compatible with its original $R$-module structure. For $r \in R$, if we treat $r$ as $f(r) \in S$ then scaling by $f(r)$ on an elementary tensor $s \otimes m$ has the effect $f(r)(s \otimes m)=f(r) s \otimes m$. Since $f(r) s$ is the definition of $r s$ (this is how we make $S$ into an $R$-module), $f(r) s \otimes m=r s \otimes m=r(s \otimes m)$. Thus $f(r)(s \otimes m)=r(s \otimes m)$, so $f(r) t=r t$ for all $t$ in $S \otimes_{R} M$ by additivity.

By exactly the same kind of argument, $M \otimes_{R} S$ with $S$ on the right has a unique $S$ module structure where $s^{\prime}(m \otimes s)=m \otimes s^{\prime} s$. So whenever we meet $S \otimes_{R} M$ or $M \otimes_{R} S$, we know they are $S$-modules in a specific way. Moreover, these two $S$-modules are naturally isomorphic: by Theorem 5.1, there is an isomorphism $\varphi: S \otimes_{R} M \rightarrow M \otimes_{R} S$ of $R$-modules where $\varphi(s \otimes m)=m \otimes s$. To show $\varphi$ is in fact an isomorphism of $S$-modules, all we need to do is check $S$-linearity since $\varphi$ is known to be additive and a bijection. To show $\varphi\left(s^{\prime} t\right)=s^{\prime} \varphi(t)$ for all $s^{\prime}$ and $t$, additivity of both sides in $t$ means we may focus on the case $t=s \otimes m$ :

$$
\varphi\left(s^{\prime}(s \otimes m)\right)=\varphi\left(\left(s^{\prime} s\right) \otimes m\right)=m \otimes s^{\prime} s=s^{\prime}(m \otimes s)=s^{\prime} \varphi(s \otimes m) .
$$

This idea of creating an $S$-module isomorphism by using a known $R$-module isomorphism that is also $S$-linear will be used many more times, so watch for it.

We must be careful to refer to $R$-linear maps and $S$-linear maps, rather than just linear maps, so that it is clear what our scalar ring is each time.
Example 6.5. In Theorem 4.5 we saw $(R / I) \otimes_{R} M \cong M / I M$ as $R$-modules by $\bar{r} \otimes m \mapsto$ $\overline{r m}$. Since $M / I M$ is naturally an $R / I$-module, and now we know $(R / I) \otimes_{R} M$ is an $R / I$ module, the $R$-module isomorphism $(R / I) \otimes_{R} M \cong M / I M$ turns out to be an $R / I$-module isomorphism too since it is $R / I$-linear (check!).

Example 6.6. Set $N=S \otimes_{R} M$, where $M$ is an $R$-module. For an ideal $J$ in $S, J N$ is an $S$-submodule of $N$ and $N / J N$ is an $S / J$-module. We have $(S / J) \otimes_{R} M \cong N / J N$ as $S / J$-modules, which generalizes the previous example (taking $S=R$ ).

To build that isomorphism, there is an $S / J$-linear mapping $f:(S / J) \otimes_{R} M \rightarrow N / J N$ where $\bar{s} \otimes m \mapsto \overline{s \otimes m}$ on elementary tensors: build it first as an $R$-linear mapping and then check it is $S$-linear, and then $S / J$-linear. In the other direction, there is an $S$-linear mapping $N \rightarrow(S / J) \otimes_{R} M$ where $s \otimes m \mapsto \bar{s} \otimes m$ on elementary tensors: build it first as an $R$-linear mapping and then check it is $S$-linear. Then show it kills $J N$, so it induces an $S$-linear mapping $g: N / J N \rightarrow(S / J) \otimes_{R} M$ that is also $S / J$-linear. Check $f$ and $g$ are inverses by looking at their values on the obvious spanning sets of their domains.

As an instance of $(S / J) \otimes_{R} M \cong N / J N$, take $S=R[X]$ and $J=X S$, so $S / J \cong R$ as $R$-modules and as $R[X]$-modules where $X$ acts on $R$ as 0 . For an $R$-module $M, N / X N=$ $N / J N \cong(S / J) \otimes_{R} M \cong R \otimes_{R} M \cong M$ as $R$-modules. So if an $R[X]$-module $N$ is the base extension of an $R$-module $M$, then we can describe $M$ up to isomorphism as $N / X N$.

Theorem 6.7. If $F$ is a free $R$-module with basis $\left\{e_{i}\right\}_{i \in I}$ then $S \otimes_{R} F$ is a free $S$-module with basis $\left\{1 \otimes e_{i}\right\}_{i \in I}$.
Proof. Since $S$ is an $R$-module, we know from Theorem 4.15 that every element of $S \otimes_{R} F$ has a unique representation in the form $\sum_{i \in I} s_{i} \otimes e_{i}$, where all but finitely many $s_{i}$ equal 0 . Since $s_{i} \otimes e_{i}=s_{i}\left(1 \otimes e_{i}\right)$ in the $S$-module structure on $S \otimes_{R} F$, every element of $S \otimes_{R} F$ is a unique $S$-linear combination $\sum s_{i}\left(1 \otimes e_{i}\right)$, which says $\left\{1 \otimes e_{i}\right\}$ is an $S$-basis of $S \otimes_{R} F$.
Example 6.8. As an $S$-module, $S \otimes_{R} R^{n}$ has $S$-basis $\left\{1 \otimes e_{1}, \ldots, 1 \otimes e_{n}\right\}$ where $\left\{e_{1}, \ldots, e_{n}\right\}$ is the standard basis of $R^{n}$, so $S^{n} \cong S \otimes_{R} R^{n}$ as $S$-modules by

$$
\left(s_{1}, \ldots, s_{n}\right) \mapsto \sum_{i=1}^{n} s_{i}\left(1 \otimes e_{i}\right)=\sum_{i=1}^{n} s_{i} \otimes e_{i}
$$

because this map is $S$-linear (check!) and sends an $S$-basis to an $S$-basis. In particular, $S \otimes_{R} R \cong S$ as $S$-modules by $s \otimes r \mapsto s r$.

For instance,

$$
\mathbf{C} \otimes_{\mathbf{R}} \mathbf{R}^{n} \cong \mathbf{C}^{n}, \quad \mathbf{C} \otimes_{\mathbf{R}} \mathrm{M}_{n}(\mathbf{R}) \cong \mathrm{M}_{n}(\mathbf{C})
$$

as $\mathbf{C}$-vector spaces, not just as $\mathbf{R}$-vector spaces. For an ideal $I$ in $R,(R / I) \otimes_{R} R^{n} \cong(R / I)^{n}$, not just as $R$-modules. as $R / I$-modules.
Example 6.9. As an $S$-module, $S \otimes_{R} R[X]$ has $S$-basis $\left\{1 \otimes X^{i}\right\}_{i \geq 0}$, so $S \otimes_{R} R[X] \cong S[X]$ as $S$-modules ${ }^{22}$ by $\sum_{i \geq 0} s_{i} \otimes X^{i} \mapsto \sum_{i \geq 0} s_{i} X^{i}$.

[^16]As particular examples, $\mathbf{C} \otimes_{\mathbf{R}} \mathbf{R}[X] \cong \mathbf{C}[X]$ as $\mathbf{C}$-vector spaces, $\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{Z}[X] \cong \mathbf{Q}[X]$ as $\mathbf{Q}$-vector spaces and $(\mathbf{Z} / p \mathbf{Z}) \otimes_{\mathbf{Z}} \mathbf{Z}[X] \cong(\mathbf{Z} / p \mathbf{Z})[X]$ as $\mathbf{Z} / p \mathbf{Z}$-vector spaces.
Example 6.10. If we treat $\mathbf{C}^{n}$ as a real vector space, then its base extension to $\mathbf{C}$ is the complex vector space $\mathbf{C} \otimes_{\mathbf{R}} \mathbf{C}^{n}$ where $c(z \otimes v)=c z \otimes v$ for $c$ in $\mathbf{C}$. Since $\mathbf{C}^{n} \cong \mathbf{R}^{2 n}$ as real vector spaces, we have a $\mathbf{C}$-vector space isomorphism

$$
\mathbf{C} \otimes_{\mathbf{R}} \mathbf{C}^{n} \cong \mathbf{C} \otimes_{\mathbf{R}} \mathbf{R}^{2 n} \cong \mathbf{C}^{2 n}
$$

That's interesting: restricting scalars on $\mathbf{C}^{n}$ to make it a real vector space and then extending scalars back up to $\mathbf{C}$ does not give us $\mathbf{C}^{n}$ back, but instead two copies of $\mathbf{C}^{n}$. The point is that when we restrict scalars, the real vector space $\mathbf{C}^{n}$ forgets it is a complex vector space. So the base extension of $\mathbf{C}^{n}$ from a real vector space to a complex vector space doesn't remember that it used to be a complex vector space.

Quite generally, if $V$ is a finite-dimensional complex vector space and we view it as a real vector space, its base extension $\mathbf{C} \otimes_{\mathbf{R}} V$ to a complex vector space is not $V$ but a direct sum of two copies of $V$. Let's do a dimension check. Set $n=\operatorname{dim}_{\mathbf{C}}(V)$, so $\operatorname{dim}_{\mathbf{R}}(V)=2 n$. Then $\operatorname{dim}_{\mathbf{R}}\left(\mathbf{C} \otimes_{\mathbf{R}} V\right)=\operatorname{dim}_{\mathbf{R}}(\mathbf{C}) \operatorname{dim}_{\mathbf{R}}(V)=2(2 n)=4 n$ and $\operatorname{dim}_{\mathbf{R}}(V \oplus V)=2 \operatorname{dim}_{\mathbf{R}}(V)=$ $2(2 n)=4 n$, so the two dimensions match. This match is of course not a proof that there is a natural isomorphism $\mathbf{C} \otimes_{\mathbf{R}} V \rightarrow V \oplus V$ of complex vector spaces. Work out such an isomorphism as an exercise. The proof had better use the fact that $V$ is already a complex vector space to make sense of $V \oplus V$ as a complex vector space.

To get our bearing on this example, let's compare an $S$-module $N$ with the $S$-module $S \otimes_{R} N$ (where $s^{\prime}(s \otimes n)=s^{\prime} s \otimes n$ ). Since $N$ is already an $S$-module, should $S \otimes_{R} N \cong N$ ? If you think so, reread Example $6.10\left(R=\mathbf{R}, S=\mathbf{C}, N=\mathbf{C}^{n}\right)$. Scalar multiplication $S \times N \rightarrow N$ is $R$-bilinear, so there is an $R$-linear map $\varphi: S \otimes_{R} N \rightarrow N$ where $\varphi(s \otimes n)=s n$. This map is also $S$-linear: $\varphi(s t)=s \varphi(t)$. To check this, since both sides are additive in $t$ it suffices to check the case of elementary tensors, and

$$
\varphi\left(s\left(s^{\prime} \otimes n\right)\right)=\varphi\left(\left(s s^{\prime}\right) \otimes n\right)=s s^{\prime} n=s\left(s^{\prime} n\right)=s \varphi\left(s^{\prime} \otimes n\right) .
$$

In the other direction, the function $\psi: N \rightarrow S \otimes_{R} N$ where $\psi(n)=1 \otimes n$ is $R$-linear but is generally not $S$-linear since $\psi(s n)=1 \otimes s n$ has no reason to be $s \psi(n)=s \otimes n$ because we're using $\otimes_{R}$, not $\otimes_{S}$. We have created natural maps $\varphi: S \otimes_{R} N \rightarrow N$ and $\psi: N \rightarrow S \otimes_{R} N$; are they inverses? It's unlikely, since $\varphi$ is $S$-linear and $\psi$ is generally not. But let's work out the composites and see what happens. In one direction,

$$
\varphi(\psi(n))=\varphi(1 \otimes n)=1 \cdot n=n .
$$

In the other direction,

$$
\psi(\varphi(s \otimes n))=\psi(s n)=1 \otimes s n \neq s \otimes n
$$

in general. So $\varphi \circ \psi$ is the identity but $\psi \circ \varphi$ is usually not the identity. Since $\varphi \circ \psi=\mathrm{id}_{N}$, $\psi$ is a section to $\varphi$, so $N$ is a direct summand of $S \otimes_{R} N$. Explicitly, $S \otimes_{R} N \cong \operatorname{ker} \varphi \oplus N$ by $s \otimes n \mapsto(s \otimes n-1 \otimes s n, s n)$ and its inverse map is $(k, n) \mapsto k+1 \otimes n$. The phenomenon that $S \otimes_{R} N$ is typically larger than $N$ when $N$ is an $S$-module can be remembered by the example $\mathbf{C} \otimes_{\mathbf{R}} \mathbf{C}^{n} \cong \mathbf{C}^{2 n}$.

Theorem 6.11. For $R$-modules $\left\{M_{i}\right\}_{i \in I}$, there is an $S$-module isomorphism

$$
S \otimes_{R} \bigoplus_{i \in I} M_{i} \cong \bigoplus_{i \in I}\left(S \otimes_{R} M_{i}\right) .
$$

Proof. This is vacuously true if $I=\emptyset$ or $R=0$, so take $I \neq \emptyset$ and $R \neq 0$. Since $S$ is an $R$-module, by Theorem 5.4 there is an $R$-module isomorphism

$$
\varphi: S \otimes_{R} \bigoplus_{i \in I} M_{i} \rightarrow \bigoplus_{i \in I}\left(S \otimes_{R} M_{i}\right)
$$

where $\varphi\left(s \otimes\left(m_{i}\right)_{i \in I}\right)=\left(s \otimes m_{i}\right)_{i \in I}$. To show $\varphi$ is an $S$-module isomorphism, we just have to check $\varphi$ is $S$-linear, since we already know $\varphi$ is additive and a bijection. It is obvious that $\varphi(s t)=s \varphi(t)$ when $t$ is an elementary tensor, and since both $\varphi(s t)$ and $s \varphi(t)$ are additive in $t$ the case of general tensors follows.

The analogue of Theorem 6.11 for direct products of $R$-modules is false. The natural $S$-linear map $S \otimes_{R} \prod_{i \in I} M_{i} \rightarrow \prod_{i \in I}\left(S \otimes_{R} M_{i}\right)$ need not be an isomorphism. Here are two examples.

- $\mathbf{Q} \otimes_{\mathbf{Z}} \prod_{i \geq 1} \mathbf{Z} / p^{i} \mathbf{Z}$ is nonzero (Remark 5.5) but $\prod_{i \geq 1}\left(\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{Z} / p^{i} \mathbf{Z}\right)$ is 0 .
- $\mathbf{Q} \otimes_{\mathbf{z}} \prod_{i \geq 1} \mathbf{Z}$ is isomorphic as a $\mathbf{Q}$-vector space not to $\prod_{i \geq 1}\left(\mathbf{Q} \otimes_{\mathbf{z}} \mathbf{Z}\right) \cong \prod_{i \geq 1} \mathbf{Q}$, but rather to the subgroup of $\prod_{i \geq 1} \mathbf{Q}$ consisting of rational sequences with a common denominator. Under the natural map $\mathbf{Q} \otimes \mathbf{Z} \prod_{i \geq 1} \mathbf{Z} \rightarrow \prod_{i \geq 1} \mathbf{Q}$, the image of an elementary tensor has coordinates with a common denominator, and each tensor in $\mathbf{Q} \otimes_{\mathbf{Z}} \prod_{i \geq 1} \mathbf{Z}$ is a finite sum of elementary tenors, so its image in $\prod_{i \geq 1} \mathbf{Q}$ is a sequence with a common denominator.
We now put base extensions to work. Let $M$ be a finitely generated $R$-module, say with $n$ generators. That is the same as saying there is a linear surjection $R^{n} \rightarrow M$. To say $M$ contains a subset of $d$ linearly independent elements is the same as saying there is a linear injection $R^{d} \hookrightarrow M$. If both $R^{n} \rightarrow M$ and $R^{d} \hookrightarrow M$, it is natural to suspect $d \leq n$, i.e., the size of a spanning set should always be an upper bound on the size of a linearly independent subset. Is it really true? If $R$ is a field, so modules are vector spaces, we can use dimension inequalities on $R^{d}, M$, and $R^{n}$ to see $d \leq n$. But if $R$ is not a field, then what? We will settle the issue in the affirmative when $R$ is a domain, by tensoring $M$ with the fraction field of $R$ to reduce to the case of vector spaces. We first tensored $R$-modules with the fraction field of $R$ as a special case of Theorem 4.27, but not much use was made of the vector space structure of the tensor product with a field. Now we exploit it.

Theorem 6.12. Let $R$ be a domain with fraction field $K$. For a finitely generated $R$-module $M, K \otimes_{R} M$ is finite-dimensional as a $K$-vector space and $\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$ is the maximal number of $R$-linearly independent elements in $M$ and is a lower bound on the size of $a$ spanning set for $M$. In particular, the size of each linearly independent subset of $M$ is less than or equal to the size of each spanning set of $M$.

Proof. If $x_{1}, \ldots, x_{n}$ is a spanning set for $M$ as an $R$-module then $1 \otimes x_{1}, \ldots, 1 \otimes x_{n}$ span $K \otimes_{R} M$ as a $K$-vector space, so $\operatorname{dim}_{K}\left(K \otimes_{R} M\right) \leq n$.

Let $y_{1}, \ldots, y_{d}$ be $R$-linearly independent in $M$. We will show $\left\{1 \otimes y_{i}\right\}$ is $K$-linearly independent in $K \otimes_{R} M$, so $d \leq \operatorname{dim}_{K}\left(K \otimes_{R} M\right)$. Suppose $\sum_{i=1}^{d} c_{i}\left(1 \otimes y_{i}\right)=0$ with $c_{i} \in K$. Write $c_{i}=a_{i} / b$ using a common denominator $b$ in $R$. Then $0=1 / b \otimes \sum_{i=1}^{d} a_{i} y_{i}$ in $K \otimes_{R} M$. By Corollary 4.28 , this implies $\sum_{i=1}^{d} a_{i} y_{i} \in M_{\text {tor }}$, so $\sum_{i=1}^{d} r a_{i} y_{i}=0$ in $M$ for some nonzero $r \in R$. By linear independence of the $y_{i}$ 's over $R$, every $r a_{i}$ is 0 , so every $a_{i}$ is 0 ( $R$ is a domain). Thus every $c_{i}=a_{i} / b$ is 0 .

It remains to prove $M$ has a linearly independent subset of size $\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$. Let $\left\{e_{1}, \ldots, e_{d}\right\}$ be a linearly independent subset of $M$, where $d$ is maximal. (Since $d \leq$
$\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$, there is a maximal $d$.) For every $m \in M,\left\{e_{1}, \ldots, e_{d}, m\right\}$ has to be linearly dependent, so there is a nontrivial $R$-linear relation

$$
a_{1} e_{1}+\cdots+a_{d} e_{d}+a m=0 .
$$

Necessarily $a \neq 0$, as otherwise all the $a_{i}$ 's are 0 by linear independence of the $e_{i}$ 's. In $K \otimes_{R} M$,

$$
\sum_{i=1}^{d} a_{i}\left(1 \otimes e_{i}\right)+a(1 \otimes m)=0
$$

and from the $K$-vector space structure on $K \otimes_{R} M$ we can solve for $1 \otimes m$ as a $K$-linear combination of the $1 \otimes e_{i}$ 's. Therefore $\left\{1 \otimes e_{i}\right\}$ spans $K \otimes_{R} M$ as a $K$-vector space. This set is also linearly independent over $K$ by the previous paragraph, so it is a basis and therefore $d=\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$.

While $M$ has at most $\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$ linearly independent elements and this upper bound is achieved, each spanning set has at least $\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$ elements but this lower bound is not necessarily reached. For example, if $R$ is not a field and $M$ is a torsion module (e.g., $R / I$ for $I$ a nonzero proper ideal) then $K \otimes_{R} M=0$ and $M$ certainly doesn't have a spanning set of size 0 if $M \neq 0$. It is also not true that finiteness of $\operatorname{dim}_{K}\left(K \otimes_{R} M\right)$ implies $M$ is finitely generated as an $R$-module. Take $R=\mathbf{Z}$ and $M=\mathbf{Q}$, so $\mathbf{Q} \otimes_{\mathbf{Z}} M=\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{Q} \cong \mathbf{Q}$ (Example 4.22), which is finite-dimensional over $\mathbf{Q}$ but $M$ is not finitely generated over $\mathbf{Z}$.

The maximal number of linearly independent elements in an $R$-module $M$, for $R$ a domain, is called the rank of $M .{ }^{23}$ This use of the word "rank" is consistent with its usage for finite free modules as the size of a basis: if $M$ is free with an $R$-basis of size $n$ then $K \otimes_{R} M$ has a $K$-basis of size $n$ by Theorem 6.7.

Example 6.13. A nonzero ideal $I$ in a domain $R$ has rank 1 . We can see this in two ways. First, any two nonzero elements in $I$ are linearly dependent over $R$, so the maximal number of $R$-linearly independent elements in $I$ is 1 . Second, $K \otimes_{R} I \cong K$ as $K$-vector spaces (in Theorem 4.23 we showed they are isomorphic as $R$-modules, but that isomorphism is also $K$-linear; check!), so $\operatorname{dim}_{K}\left(K \otimes_{R} I\right)=1$.

Example 6.14. For a domain $R$ with fraction field $K$, a finitely generated $R$-module $M$ has rank 0 if and only if it is a torsion module, since $K \otimes_{R} M=0$ if and only if $M$ is torsion.

Since $K \otimes_{R} M \cong K \otimes_{R}\left(M / M_{\text {tor }}\right)$ as $K$-vector spaces (the isomorphism between them as $R$-modules in Theorem 4.27 is easily checked to be $K$-linear - check!), $M$ and $M / M_{\text {tor }}$ have the same rank.

We return to general $R$, no longer a domain, and see how to make the tensor product of an $R$-module and $S$-module into an $S$-module.

Theorem 6.15. Let $M$ be an $R$-module and $N$ be an $S$-module.
(1) The additive group $M \otimes_{R} N$ has a unique structure of $S$-module such that $s(m \otimes n)=$ $m \otimes s n$ for $s \in S$. This is compatible with the $R$-module structure in the sense that $r t=f(r) t$ for $r \in R$ and $t \in M \otimes_{R} N$.
(2) The $S$-module $M \otimes_{R} N$ is isomorphic to $\left(S \otimes_{R} M\right) \otimes_{S} N$ by sending $m \otimes_{R} n$ to $\left(1 \otimes_{R} m\right) \otimes_{S} n$.

[^17]The point of part 2 is that it shows how the $S$-module structure on $M \otimes_{R} N$ can be described as an ordinary $S$-module tensor product by base extending $M$ to an $S$-module $S \otimes_{R} M$. Part 2 has both $R$-module and $S$-module tensor products, and it is the first time that we must decorate the tensor product sign explicitly. Up to now it was actually unnecessary, as all the tensor products were over $R$.

Writing $S \otimes_{R} M$ as $M \otimes_{R} S$ makes the isomorphism in part 2 notationally obvious, since it becomes $\left(M \otimes_{R} S\right) \otimes_{S} N \cong M \otimes_{R} N$; this is similar to the "proof" of the chain rule in differential calculus, $d y / d x=(d y / d u)(d u / d x)$, by cancellation of $d u$ in the notation. This kind of notational trick will be proved in greater generality in Theorem 6.25(3).

Proof. (1) This is similar to the proof of Theorem 6.4 (which is the special case $N=S$ ). We just sketch the idea.

Since every tensor is a sum of elementary tensors, declaring how $s \in S$ scales elementary tensors in $M \otimes_{R} N$ determines its scaling on all tensors. To show the rule $s(m \otimes n)=m \otimes s n$ really corresponds to an $S$-module structure, for each $s \in S$ we consider the function $M \times N \rightarrow M \otimes_{R} N$ given by $(m, n) \mapsto m \otimes s n$. This is $R$-bilinear in $m$ and $n$, so there is an $R$-linear map $\mu_{s}: M \otimes_{R} N \rightarrow M \otimes_{R} N$ such that $\mu_{s}(m \otimes n)=m \otimes s n$ on elementary tensors. Define a multiplication $S \times\left(M \otimes_{R} N\right) \rightarrow M \otimes_{R} N$ by st $:=\mu_{s}(t)$. It is left to the reader to check that the maps $\mu_{s}$ on $M \otimes_{R} N$, as $s$ varies, satisfy the scaling axioms that make $M \otimes_{R} N$ an $S$-module.

To check $r t=f(r) t$ for $r \in R$ and $t \in M \otimes_{R} N$, both sides are additive in $t$ so it suffices to check equality when $t=m \otimes n$ is an elementary tensor. In that case $r(m \otimes n)=m \otimes r n=$ $m \otimes f(r) n=f(r)(m \otimes n)$.
(2) Let $M \times N \rightarrow\left(S \otimes_{R} M\right) \otimes_{S} N$ by $(m, n) \mapsto\left(1 \otimes_{R} m\right) \otimes_{S} n$. We want to check this is $R$-bilinear. Biadditivity is clear. For $R$-scaling, we have

$$
\left(1 \otimes_{R} r m\right) \otimes_{S} n=\left(r\left(1 \otimes_{R} m\right)\right) \otimes_{S} n=\left(f(r)\left(1 \otimes_{R} m\right)\right) \otimes_{S} n=f(r)\left(\left(1 \otimes_{R} m\right) \otimes_{S} n\right)
$$

and

$$
\left(1 \otimes_{R} m\right) \otimes_{S} r n=\left(1 \otimes_{R} m\right) \otimes_{S} f(r) n=f(r)\left(\left(1 \otimes_{R} m\right) \otimes_{S} n\right) .
$$

Now the universal mapping property of tensor products gives an $R$-linear map $\varphi: M \otimes_{R} N \rightarrow$ $\left(S \otimes_{R} M\right) \otimes_{S} N$ where $\varphi\left(m \otimes_{R} n\right)=\left(1 \otimes_{R} m\right) \otimes_{S} n$. This is exactly the map we were looking for, but we only know it is $R$-linear so far. It is also $S$-linear: $\varphi(s t)=s \varphi(t)$. To check this, it suffices by additivity of $\varphi$ to focus on the case of an elementary tensor:

$$
\varphi\left(s\left(m \otimes_{R} n\right)\right)=\varphi\left(m \otimes_{R} s n\right)=\left(1 \otimes_{R} m\right) \otimes_{S} s n=s\left(\left(1 \otimes_{R} m\right) \otimes_{S} n\right)=s \varphi\left(m \otimes_{R} n\right)
$$

To show $\varphi$ is an isomorphism, we create an inverse map $\left(S \otimes_{R} M\right) \otimes_{S} N \rightarrow M \otimes_{R} N$. The function $S \times M \times N \rightarrow M \otimes_{R} N$ given by $(s, m, n) \mapsto m \otimes s n$ is $R$-trilinear, so by Theorem 5.6 there is an $R$-bilinear map $B:\left(S \otimes_{R} M\right) \times N \rightarrow M \otimes_{R} N$ where $B(s \otimes m, n)=m \otimes s n$. This function is in fact $S$-bilinear:

$$
B(s t, n)=s B(t, n), \quad B(t, s n)=s B(t, n) .
$$

To check these equations, the additivity of both sides of the equations in $t$ reduces us to case when $t$ is an elementary tensor. Writing $t=s^{\prime} \otimes m$,

$$
B\left(s\left(s^{\prime} \otimes m\right), n\right)=B\left(s s^{\prime} \otimes m, n\right)=m \otimes s s^{\prime} n=m \otimes s\left(s^{\prime} n\right)=s\left(m \otimes s^{\prime} n\right)=s B\left(s^{\prime} \otimes m, n\right)
$$

and

$$
B\left(s^{\prime} \otimes m, s n\right)=m \otimes s^{\prime}(s n)=m \otimes s\left(s^{\prime} n\right)=s\left(m \otimes s^{\prime} n\right)=s B\left(s^{\prime} \otimes m, n\right)
$$

Now the universal mapping property of the tensor product for $S$-modules tells us there is an $S$-linear map $\psi:\left(S \otimes_{R} M\right) \otimes_{S} N \rightarrow M \otimes_{R} N$ such that $\psi(t \otimes n)=B(t, n)$.

It is left to the reader to check $\varphi \circ \psi$ and $\psi \circ \varphi$ are identity functions, so $\varphi$ is an $S$-module isomorphism.

In addition to $M \otimes_{R} N$ being an $S$-module because $N$ is, the tensor product $N \otimes_{R} M$ in the other order has a unique $S$-module structure where $s(n \otimes m)=s n \otimes m$, and this is proved in a similar way.

Example 6.16. For an $S$-module $N$, let's show $R^{k} \otimes_{R} N \cong N^{k}$ as $S$-modules. By Theorem 5.4, $R^{k} \otimes_{R} N \cong\left(R \otimes_{R} N\right)^{k} \cong N^{k}$ as $R$-modules, an explicit isomorphism $\varphi: R^{k} \otimes_{R} N \rightarrow N^{k}$ being $\varphi\left(\left(r_{1}, \ldots, r_{k}\right) \otimes n\right)=\left(r_{1} n, \ldots, r_{k} n\right)$. Let's check $\varphi$ is $S$-linear: $\varphi(s t)=s \varphi(t)$. Both sides are additive in $t$, so we only need to check when $t$ is an elementary tensor:

$$
\varphi\left(s\left(\left(r_{1}, \ldots, r_{k}\right) \otimes n\right)\right)=\varphi\left(\left(r_{1}, \ldots, r_{k}\right) \otimes s n\right)=\left(r_{1} s n, \ldots, r_{k} s n\right)=s \varphi\left(\left(r_{1}, \ldots, r_{k}\right) \otimes n\right) .
$$

To reinforce the $S$-module isomorphism

$$
\begin{equation*}
M \otimes_{R} N \cong\left(S \otimes_{R} M\right) \otimes_{S} N \tag{6.3}
\end{equation*}
$$

from Theorem 6.15(2), let's write out the isomorphism in both directions on appropriate tensors:

$$
m \otimes_{R} n \mapsto\left(1 \otimes_{R} m\right) \otimes_{S} n, \quad\left(s \otimes_{R} m\right) \otimes_{S} n \mapsto m \otimes_{R} s n .
$$

Corollary 6.17. If $M$ and $M^{\prime}$ are isomorphic $R$-modules, and $N$ is an $S$-module, then $M \otimes_{R} N$ and $M^{\prime} \otimes_{R} N$ are isomorphic $S$-modules, as are $N \otimes_{R} M$ and $N \otimes_{R} M^{\prime}$.
Proof. We will show $M \otimes_{R} N \cong M^{\prime} \otimes_{R} N$ as $S$-modules. The other one is similar.
Let $\varphi: M \rightarrow M^{\prime}$ be an $R$-module isomorphism. To write down an $S$-module isomorphism $M \otimes_{R} N \rightarrow M^{\prime} \otimes_{R} N$, we will write down an $R$-module isomorphism that is also $S$-linear. Let $M \times N \rightarrow M^{\prime} \otimes_{R} N$ by $(m, n) \mapsto \varphi(m) \otimes n$. This is $R$-bilinear (check!), so we get an $R$-linear map $\Phi: M \otimes_{R} N \rightarrow M^{\prime} \otimes_{R} N$ such that $\Phi(m \otimes n)=\varphi(m) \otimes n$. This is also $S$-linear: $\Phi(s t)=s \Phi(t)$. Since $\Phi$ is additive, it suffices to check this when $t=m \otimes n$ :

$$
\Phi(s(m \otimes n))=\Phi(m \otimes s n)=\varphi(m) \otimes s n=s(\varphi(m) \otimes n)=s \Phi(m \otimes n) .
$$

Using the inverse map to $\varphi$ we get an $R$-linear map $\Psi: M^{\prime} \otimes_{R} N \rightarrow M \otimes_{R} N$ that is also $S$-linear, and a computation on elementary tensors shows $\Phi$ and $\Psi$ are inverses of each other.

Example 6.18. We can use tensor products to prove the well-definedness of ranks of finite free $R$-modules when $R \neq 0$. Suppose $R^{m} \cong R^{n}$ as $R$-modules. Pick a maximal ideal $\mathfrak{m}$ in $R$ (Zorn's lemma) and $R / \mathfrak{m} \otimes_{R} R^{m} \cong R / \mathfrak{m} \otimes_{R} R^{n}$ as $R / \mathfrak{m}$-vector spaces by Corollary 6.17. Therefore $(R / \mathfrak{m})^{m} \cong(R / \mathfrak{m})^{n}$ as $R / \mathfrak{m}$-vector spaces (Example 6.8), so taking dimensions of both sides over $R / \mathfrak{m}$ tells us $m=n$.

Here's a conundrum. If $N$ and $N^{\prime}$ are both $S$-modules, then we can make $N \otimes_{R} N^{\prime}$ into an $S$-module in two ways: $s\left(n \otimes_{R} n^{\prime}\right)=s n \otimes_{R} n^{\prime}$ and $s\left(n \otimes_{R} n^{\prime}\right)=n \otimes_{R} s n^{\prime}$. In the first $S$-module structure on $N \otimes_{R} N^{\prime}, N^{\prime}$ only matters as an $R$-module. In the second $S$-module structure, $N$ only matters as an $R$-module. These two $S$-module structures on $N \otimes_{R} N^{\prime}$ are not generally the same because the tensor product is $\otimes_{R}$, not $\otimes_{S}$, so $s n \otimes_{R} n^{\prime}$ need not equal $n \otimes_{R} s n^{\prime}$. But are the two $S$-module structures on $N \otimes_{R} N^{\prime}$ at least isomorphic to each other? In general, no.

Example 6.19. Let $R=\mathbf{Z}$ and $S=\mathbf{Z}[\sqrt{d}]$ for nonsquare $d \equiv 1 \bmod 4$. Let $I$ be the ideal $(2,1+\sqrt{d})$ in $S$, so as a $\mathbf{Z}$-module $I=\mathbf{Z} 2+\mathbf{Z}(1+\sqrt{d})$. We will look at the $S$-module structures on $S \otimes_{\mathbf{z}} I$ coming from scaling by $S$ on the left and on the right.

As Z-modules, $S$ and $I$ are free of rank 2 . When $S \otimes_{\mathbf{z}} I$ is an $S$-module by scaling by $S$ on the left, $I$ only matters as a Z-module, so $S \otimes_{\mathbf{Z}} I \cong S \otimes_{\mathbf{Z}} \mathbf{Z}^{2}$ as $S$-modules by Corollary 6.17. By Example 6.8, $S \otimes_{\mathbf{Z}} \mathbf{Z}^{2} \cong S^{2}$ as $S$-modules. By making $S \otimes_{\mathbf{Z}} I$ into an $S$-module by scaling by $S$ on the right, $S \otimes_{\mathbf{Z}} I \cong \mathbf{Z}^{2} \otimes_{\mathbf{Z}} I \cong I \oplus I$ as $S$-modules. If $I \oplus I \not \not S^{2}$ as $S$-modules then $S \otimes \mathbf{z} I$ has different $S$-module structures by $S$-scaling on the left and right.

The crucial property of $I$ is that (check!) $I^{2}=2 I$, where $I^{2}$ means the product $I I$ as an ideal. That implies $I$ is not a principal ideal in $S$ : if $I=\alpha S$ then $I^{2}=\alpha^{2} S$, so $\alpha^{2} S=2 \alpha S$, which implies $\alpha S=2 S$. However, $2 S$ has index 4 in $S$ while $I$ has index 2 in $S$, so $I$ is nonprincipal. Thus $I$ is not principal, so it is not a free $S$-module. Is it then obvious that $I \oplus I$ is not a free $S$-module? No! A direct sum of two nonfree modules can be free. For instance, in $\mathbf{Z}[\sqrt{-5}]$ the ideals $I=(3,1+\sqrt{-5})$ and $J=(3,1-\sqrt{-5})$ are both nonprincipal but it can be shown that $I \oplus J \cong \mathbf{Z}[\sqrt{-5}] \oplus \mathbf{Z}[\sqrt{-5}]$ as $\mathbf{Z}[\sqrt{-5}]$-modules. The reason a direct sum of non-free modules can sometimes be free is that there is more room to move around in a direct sum than just within the direct summands, and this extra room might contain a basis. So showing $I \oplus I$ is not a free $S$-module requires work.

Using more advanced tools in multilinear algebra (specifically, exterior powers), one can show that if $I \oplus I \cong S^{2}$ as $S$-modules then $I \otimes_{S} I \cong S$ as $S$-modules. Then since multiplication gives a surjective $S$-linear map $I \otimes_{S} I \rightarrow I^{2}$ (where $x \otimes y \mapsto x y$ ), there would be a surjective $S$-linear map $S \rightarrow I^{2}$, which means $I^{2}$ would be a principal ideal. However, $I^{2}=2 I$ and $I$ is not principal, so $I^{2}$ is not principal.

The lesson from this example is that if you want $N \otimes_{R} N^{\prime}$ to be an $S$-module where $N$ and $N^{\prime}$ are $S$-modules, you have to specify whether $S$ scales on the left or the right. That two $S$-modules structures on $N \otimes_{R} N^{\prime}$ are the same or at least isomorphic needs a proof. Here is one such example, where $R$ is a domain and $S=K$ is its fraction field.
Theorem 6.20. Let $R$ be a domain, with fraction field $K$. For $K$-vector spaces $V$ and $W$, the $K$-vector space structures on $V \otimes_{R} W$ using $K$-scaling on either the $V$ or $W$ factor are the same.
Proof. The two $K$-vector space structures on $V \otimes_{R} W$ are based on either the formula $x\left(v \otimes_{R} w\right)=x v \otimes_{R} w$ on elementary tensors or the formula $x\left(v \otimes_{R} w\right)=v \otimes_{R} x w$ on elementary tensors, where $x \in K$ and we write $\otimes_{R}$ rather than $\otimes$ in the elementary tensors for emphasis. ${ }^{24}$ Proving that the two $K$-vector space structures on $V \otimes_{R} W$ agree amounts to showing $x v \otimes_{R} w=v \otimes_{R} x w$ for all $x \in K, v \in V$, and $w \in W$. This is something we dealt with back in the proof of Theorem 4.21, and now we'll apply that argument again.

Write $x=a / b$ with $a, b \in R$ and $b \neq 0$. Then $(x v) \otimes_{R} w$ equals

$$
\left(\frac{a}{b} v\right) \otimes_{R} w=a\left(\frac{1}{b} v\right) \otimes_{R} w=\frac{1}{b} v \otimes_{R} a w=\frac{1}{b} v \otimes_{R} b\left(\frac{a}{b} w\right)=b\left(\frac{1}{b} v\right) \otimes_{R} \frac{a}{b} w=v \otimes_{R} \frac{a}{b} w,
$$

which is $v \otimes_{R} x w$.
It would have been wrong to complete the proof by immediately writing $x v \otimes_{R} w=$ $v \otimes_{R} x w$, because we are working with an $R$-module tensor product and the scalar $x$ is

[^18]not limited to $R$. We can say in one step that $x v \otimes_{R} w=v \otimes_{R} x w$ when $x \in R$, but to say this holds when $x \in K$ needed justification. (For comparison, in $\mathbf{C} \otimes_{\mathbf{R}} \mathbf{C}$ we have $1 \otimes_{\mathbf{R}} i \neq i \otimes_{\mathbf{R}} 1$ since these are different members of a basis. More generally, check using bases that $z \otimes_{\mathbf{R}} i w \neq i z \otimes_{\mathbf{R}} w$ in $\mathbf{C} \otimes_{\mathbf{R}} \mathbf{C}$ except when $z$ or $w$ is 0 . This doesn't violate Theorem 6.20 since $\mathbf{C}$ is not the fraction field of $\mathbf{R}$.)
Corollary 6.21. With notation as in Theorem 6.20, $V \otimes_{R} W \cong V \otimes_{K} W$ as K-vector spaces by $v \otimes_{R} w \mapsto v \otimes_{K} w$.

There is no ambiguity about what we mean by $V \otimes_{R} W$ as a $K$-vector space, since the $K$-scaling via $V$ or $W$ is exactly the same by Theorem 6.20.
Proof. We will give two proofs.
The mapping $V \times W \rightarrow V \otimes_{K} W$ given by $(v, w) \mapsto v \otimes_{K} w$ is $R$-bilinear, so there is a unique $R$-linear mapping $\varphi: V \otimes_{R} W \rightarrow V \otimes_{K} W$ given by $\varphi\left(v \otimes_{R} w\right)=v \otimes_{K} w$ on elementary tensors. To show $\varphi$ is $K$-linear, it suffices to check $\varphi(x t)=x \varphi(t)$ when $t$ is an elementary tensor, so we want to check $\varphi\left(x\left(v \otimes_{R} w\right)\right)=x\left(v \otimes_{K} w\right)$. By the definition of the $K$-vector space structure on $V \otimes_{R} W, \varphi\left(x\left(v \otimes_{R} w\right)\right)=\varphi\left((x v) \otimes_{R} w\right)=(x v) \otimes_{K} w$, which is $x\left(v \otimes_{K} w\right)$. (We could also say $\varphi\left(x\left(v \otimes_{R} w\right)\right)=\varphi\left(v \otimes_{R} x w\right)=v \otimes_{K} x w$, which is $x\left(v \otimes_{K} w\right)$.)

The mapping $V \times W \rightarrow V \otimes_{R} W$ given by $(v, w) \mapsto v \otimes_{R} w$ is not just $R$-bilinear, but $K$-bilinear. For example, $(x v, w) \mapsto(x v) \otimes_{R} w=x\left(v \otimes_{R} w\right)$. Thus we get a $K$-linear map $\psi: V \otimes_{K} W \mapsto V \otimes_{R} W$ by $\psi\left(v \otimes_{K} w\right)=v \otimes_{R} w$. Since $\varphi \circ \psi$ and $\psi \circ \varphi$ are both additive and fix all elementary tensors (in $V \otimes_{K} W$ and $V \otimes_{R} W$, respectively), they fix all tensors and thus $\varphi$ and $\psi$ are inverses. Therefore $\varphi$ is an isomorphism of $K$-vector spaces.

Another reason $V \otimes_{R} W \cong V \otimes_{K} W$ as $K$-vector spaces is that $V \otimes_{R} W$ satisfies the universal mapping property of $V \otimes_{K} W$ ! Let's check this. The canonical $R$-bilinear map $V \times W \rightarrow V \otimes_{R} W$ is not just $R$-bilinear, but $K$-bilinear (why?). Then for each $K$-vector space $U$ and $K$-bilinear map $B: V \times W \rightarrow U$, since $B$ is $R$-bilinear the universal mapping property of $V \otimes_{R} W$ tells us that there is a unique $R$-linear map $L$ making the diagram

commute, and on account of the fact that $U$ and $V \otimes_{R} W$ are already $K$-vector spaces you can check that $L$ is in fact $K$-linear (and is the only $K$-linear map that can fit into the above commutative diagram). Two solutions of a universal mapping property are uniquely isomorphic to each other, so $V \otimes_{R} W \cong V \otimes_{K} W$. More specifically, using for $B$ the canonical $K$-bilinear map $V \times W \rightarrow V \otimes_{K} W$ implies that the diagram

commutes, and by universality the vertical map has to be an isomorphism.
Example 6.22. We saw in Example 4.29 that $\mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Z}) \cong \mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Q})$ as $\mathbf{Z}$-modules. Both $\mathbf{R}$ and $\mathbf{R} / \pi \mathbf{Q}$ are $\mathbf{Q}$-vector spaces, so $\mathbf{R} \otimes_{\mathbf{z}}(\mathbf{R} / \pi \mathbf{Q})$ is a $\mathbf{Q}$-vector space using $\mathbf{Q}$ scaling on either $\mathbf{R}$ or $\mathbf{R} / \pi \mathbf{Q}$. By Corollary $6.21, \mathbf{R} \otimes \mathbf{z}(\mathbf{R} / \pi \mathbf{Q}) \cong \mathbf{R} \otimes_{\mathbf{Q}}(\mathbf{R} / \pi \mathbf{Q})$ as $\mathbf{Q}$-vector spaces. Different descriptions of the Dehn invariant used to solve Hilbert's 3rd problem place values of that invariant in $\mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Z}), \mathbf{R} \otimes_{\mathbf{Z}}(\mathbf{R} / \pi \mathbf{Q})$, or $\mathbf{R} \otimes_{\mathbf{Q}}(\mathbf{R} / \pi \mathbf{Q})$, and the choice doesn't really matter since they are essentially the same thing.
Example 6.23. Since $\mathbf{R}$ is a $\mathbf{Q}$-vector space, $\mathbf{R} \otimes_{\mathbf{Z}} \mathbf{R} \cong \mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ as $\mathbf{Q}$-vector spaces by $x \otimes_{\mathbf{z}} y \mapsto x \otimes_{\mathbf{Q}} y$. Is there a "formula" for $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ ? Yes and no. Since $\mathbf{R}$ is uncountable, if $\left\{e_{i}\right\}$ is a $\mathbf{Q}$-basis of $\mathbf{R}$, then this basis has cardinality equal to the cardinality of $\mathbf{R}$, and $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ has $\mathbf{Q}$-basis $\left\{e_{i} \otimes e_{j}\right\}$, whose cardinality is also the same as $\mathbf{R}$, so we could say $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ is isomorphic to $\mathbf{R}$ as $\mathbf{Q}$-vector spaces. However, this isomorphism is completely nonconstructive.

Recalling that $\mathbf{R} \otimes_{\mathbf{R}} \mathbf{R} \cong \mathbf{R}$ as $\mathbf{R}$-vector spaces by $x \otimes_{\mathbf{R}} y \mapsto x y$, might the $\mathbf{Q}$-linear map $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R} \rightarrow \mathbf{R}$ given by $x \otimes_{\mathbf{Q}} y \mapsto x y$ on elementary tensors be an isomorphism? It is obviously surjective, but this map is far from being injective. For example, since $\pi$ is transcendental its powers $1, \pi, \pi^{2}, \ldots$ are linearly independent over $\mathbf{Q}$, so the tensors $\pi^{i} \otimes_{\mathbf{Q}} \pi^{j}$ in $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ are linearly independent over $\mathbf{Q}$. (Zorn's lemma lets us enlarge the powers of $\pi$ to a $\mathbf{Q}$-basis of $\mathbf{R}$, so the tensors $\pi^{i} \otimes_{\mathbf{Q}} \pi^{j}$ are part of a $\mathbf{Q}$-basis by Theorem 4.9 and thus are linearly independent.) Then for $n \geq 2$ the tensor $\pi^{n} \otimes 1+\pi^{n-1} \otimes \pi+\cdots+\pi \otimes \pi^{n-1}-(n-1)\left(1 \otimes \pi^{n}\right)$ in $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ is nonzero and its image in $\mathbf{R}$ is $(n-1) \pi^{n}-(n-1) \pi^{n}=0$.

Another failed attempt at trying to make $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ look like $\mathbf{R}$ concretely comes from treating $\mathbf{R} \otimes_{\mathbf{Q}} \mathbf{R}$ as a real vector space using scaling on the left (or on the right, but that is a different scaling structure since $\pi \otimes 1 \neq 1 \otimes \pi)$. Its dimension over $\mathbf{R}$ is infinite by Theorem 6.7, which is pretty far from the behavior of $\mathbf{R}$ as a real vector space.

Remark 6.24. Theorem 6.20 and its corollary remain true, by the same proofs, with localizations in places of fraction fields. If $R$ is a ring, $D$ is a multiplicative subset of $R$, and $N$ and $N^{\prime}$ are $D^{-1} R$-modules, then the two $D^{-1} R$-module structures on $N \otimes_{R} N^{\prime}$, using $D^{-1} R$-scaling on either $N$ or $N^{\prime}$, are the same: for $x \in D^{-1} R, x n \otimes_{R} n^{\prime}=n \otimes_{R} x n^{\prime}$. Moreover, the natural $D^{-1} R$-module mapping $N \otimes_{R} N^{\prime} \rightarrow N \otimes_{D^{-1} R} N^{\prime}$ determined by $n \otimes_{R} n^{\prime} \mapsto n \otimes_{D^{-1} R} n^{\prime}$ on elementary tensors is an isomorphism of $D^{-1} R$-modules.

The next theorem collects a number of earlier tensor product isomorphisms for $R$-modules and shows the same maps are $S$-module isomorphisms when one of the $R$-modules in the tensor product is an $S$-module.
Theorem 6.25. Let $M$ and $M^{\prime}$ be $R$-modules and $N$ and $N^{\prime}$ be $S$-modules.
(1) There is a unique $S$-module isomorphism

$$
M \otimes_{R} N \rightarrow N \otimes_{R} M
$$

where $m \otimes n \mapsto n \otimes m$. In particular, $S \otimes_{R} M$ and $M \otimes_{R} S$ are isomorphic $S$-modules.
(2) There are unique $S$-module isomorphisms

$$
\left(M \otimes_{R} N\right) \otimes_{R} M^{\prime} \rightarrow N \otimes_{R}\left(M \otimes_{R} M^{\prime}\right)
$$

where $(m \otimes n) \otimes m^{\prime} \mapsto n \otimes\left(m \otimes m^{\prime}\right)$ and

$$
\left(M \otimes_{R} N\right) \otimes_{R} M^{\prime} \cong M \otimes_{R}\left(N \otimes_{R} M^{\prime}\right)
$$

where $(m \otimes n) \otimes m^{\prime} \mapsto m \otimes\left(n \otimes m^{\prime}\right)$.
(3) There is a unique $S$-module isomorphism

$$
\left(M \otimes_{R} N\right) \otimes_{S} N^{\prime} \rightarrow M \otimes_{R}\left(N \otimes_{S} N^{\prime}\right)
$$

where $(m \otimes n) \otimes n^{\prime} \mapsto m \otimes\left(n \otimes n^{\prime}\right)$.
(4) There is a unique $S$-module isomorphism

$$
N \otimes_{R}\left(M \oplus M^{\prime}\right) \rightarrow\left(N \otimes_{R} M\right) \oplus\left(N \otimes_{R} M^{\prime}\right)
$$

where $n \otimes\left(m, m^{\prime}\right) \mapsto(n, m) \otimes\left(n, m^{\prime}\right)$.
In the first, second, and fourth parts, we are using $R$-module tensor products only and then endowing them with $S$-module structure from one of the factors being an $S$-module (Theorem 6.15). In the third part we have both $\otimes_{R}$ and $\otimes_{S}$.

Proof. There is a canonical $R$-module isomorphism $M \otimes_{R} N \rightarrow N \otimes_{R} M$ where $m \otimes n \mapsto$ $n \otimes m$. This map is $S$-linear using the $S$-module structure on both sides (check!), so it is an $S$-module isomorphism. This settles part 1 .

Part 2, like part 1, only uses $R$-module tensor products, so there is an $R$-module isomorphism $\varphi:\left(M \otimes_{R} N\right) \otimes_{R} M^{\prime} \rightarrow N \otimes_{R}\left(M \otimes_{R} M^{\prime}\right)$ where $\varphi\left((m \otimes n) \otimes m^{\prime}\right)=n \otimes\left(m \otimes m^{\prime}\right)$. Using the $S$-module structure on $M \otimes_{R} N,\left(M \otimes_{R} N\right) \otimes_{R} M^{\prime}$, and $N \otimes_{R}\left(M \otimes_{R} M^{\prime}\right), \varphi$ is $S$-linear (check!), so it is an $S$-module isomorphism. To derive $\left(M \otimes_{R} N\right) \otimes_{R} M^{\prime} \cong M \otimes_{R}\left(N \otimes_{R} M^{\prime}\right)$ from $\left(M \otimes_{R} N\right) \otimes_{R} M^{\prime} \cong N \otimes_{R}\left(M \otimes_{R} M^{\prime}\right)$, use a few commutativity isomorphisms.

Part 3 resembles associativity of tensor products. We will in fact derive part 3 from such associativity for $\otimes_{S}$ :

$$
\begin{aligned}
\left(M \otimes_{R} N\right) \otimes_{S} N^{\prime} & \cong\left(\left(S \otimes_{R} M\right) \otimes_{S} N\right) \otimes_{S} N^{\prime} \text { by }(6.3) \\
& \cong\left(S \otimes_{R} M\right) \otimes_{S}\left(N \otimes_{S} N^{\prime}\right) \text { by associativity of } \otimes_{S} \\
& \cong M \otimes_{R}\left(N \otimes_{S} N^{\prime}\right) \text { by }(6.3) .
\end{aligned}
$$

These successive $S$-module isomorphisms have the effect

$$
\begin{aligned}
(m \otimes n) \otimes n^{\prime} & \mapsto((1 \otimes m) \otimes n) \otimes n^{\prime} \\
& \mapsto(1 \otimes m) \otimes\left(n \otimes n^{\prime}\right) \\
& \mapsto m \otimes\left(n \otimes n^{\prime}\right),
\end{aligned}
$$

which is what we wanted.
For part 4, there is an $R$-module isomorphism $N \otimes_{R}\left(M \oplus M^{\prime}\right) \rightarrow\left(N \otimes_{R} M\right) \oplus\left(N \otimes_{R} M^{\prime}\right)$ by Theorem 5.4. Now it's just a matter of checking this map is $S$-linear using the $S$-module structure on both sides coming from $N$ being an $S$-module, and this is left to the reader. As an alternate proof, we have a chain of $S$-module isomorphisms

$$
\begin{aligned}
N \otimes_{R}\left(M \oplus M^{\prime}\right) & \cong N \otimes_{S}\left(S \otimes_{R}\left(M \oplus M^{\prime}\right)\right) \text { by part } 1 \text { and }(6.3) \\
& \cong N \otimes_{S}\left(\left(S \otimes_{R} M\right) \oplus\left(S \otimes_{R} M^{\prime}\right)\right) \text { by Theorem 6.11 } \\
& \cong\left(N \otimes_{S}\left(S \otimes_{R} M\right)\right) \oplus\left(N \otimes_{S}\left(S \otimes_{R} M^{\prime}\right)\right) \text { by Theorem } 5.4 \\
& \cong\left(N \otimes_{R} M\right) \oplus\left(N \otimes_{R} M^{\prime}\right) \text { by part } 1 \text { and }(6.3) .
\end{aligned}
$$

Of course one needs to trace through these isomorphisms to check the overall result has the effect intended on elementary tensors, and it does (exercise).

The last part of Theorem 6.25 extends to arbitrary direct sums: the natural $R$-module isomorphism $N \otimes_{R} \bigoplus_{i \in I} M_{i} \cong \bigoplus_{i \in I}\left(N \otimes_{R} M_{i}\right)$ is also an $S$-module isomorphism.

As an application of Theorem 6.25, we can show the base extension of an $R$-module tensor product "is" the $S$-module tensor product of the base extensions:
Corollary 6.26. For $R$-modules $M$ and $M^{\prime}$, there is a unique $S$-module isomorphism

$$
S \otimes_{R}\left(M \otimes_{R} M^{\prime}\right) \rightarrow\left(S \otimes_{R} M\right) \otimes_{S}\left(S \otimes_{R} M^{\prime}\right)
$$

where $s \otimes_{R}\left(m \otimes_{R} m^{\prime}\right) \mapsto s\left(\left(1 \otimes_{R} m\right) \otimes_{S}\left(1 \otimes_{R} m^{\prime}\right)\right)$.
Proof. Since $M \otimes_{R} M^{\prime}$ is additively spanned by all $m \otimes m^{\prime}, S \otimes_{R}\left(M \otimes_{R} M^{\prime}\right)$ is additively spanned by all $s \otimes_{R}\left(m \otimes_{R} m^{\prime}\right)$. Therefore an $S$-linear (or even additive) map out of $S \otimes_{R}\left(M \otimes_{R} M^{\prime}\right)$ is determined by its values on the tensors $s \otimes_{R}\left(m \otimes_{R} m^{\prime}\right)$.

We have the $S$-module isomorphisms

$$
\begin{aligned}
S \otimes_{R}\left(M \otimes_{R} M^{\prime}\right) & \cong M \otimes_{R}\left(S \otimes_{R} M^{\prime}\right) \text { by Theorem 6.25(2) } \\
& \cong\left(S \otimes_{R} M\right) \otimes_{S}\left(S \otimes_{R} M^{\prime}\right) \text { by }(6.3) .
\end{aligned}
$$

The effect of these isomorphisms on $s \otimes_{R}\left(m \otimes_{R} m^{\prime}\right)$ is

$$
\begin{aligned}
s \otimes_{R}\left(m \otimes_{R} m^{\prime}\right) & \mapsto m \otimes_{R}\left(s \otimes_{R} m^{\prime}\right) \\
& \mapsto\left(1 \otimes_{R} m\right) \otimes_{S}\left(s \otimes_{R} m^{\prime}\right) \\
& =\left(1 \otimes_{R} m\right) \otimes_{S} s\left(1 \otimes_{R} m^{\prime}\right) \\
& =s\left(\left(1 \otimes_{R} m\right) \otimes_{S}\left(1 \otimes_{R} m^{\prime}\right)\right),
\end{aligned}
$$

as desired. The effect of the inverse isomorphism on $\left(s_{1} \otimes_{R} m\right) \otimes_{S}\left(s_{2} \otimes_{R} m^{\prime}\right)$ is

$$
\begin{aligned}
\left(s_{1} \otimes_{R} m\right) \otimes_{S}\left(s_{2} \otimes_{R} m^{\prime}\right) & \mapsto m \otimes_{R} s_{1}\left(s_{2} \otimes_{R} m^{\prime}\right) \\
& =m \otimes_{R}\left(\left(s_{1} s_{2}\right) \otimes_{R} m^{\prime}\right) \\
& \mapsto s_{1} s_{2} \otimes_{R}\left(m \otimes_{R} m^{\prime}\right) .
\end{aligned}
$$

Theorem 6.26 could also be proved by showing the $S$-module $S \otimes_{R}\left(M \otimes_{R} M^{\prime}\right)$ has the universal mapping property of $\left(S \otimes_{R} M\right) \otimes_{S}\left(S \otimes_{R} M^{\prime}\right)$ as a tensor product of $S$-modules. That is left as an exercise.

Corollary 6.27. For $R$-modules $M_{1}, \ldots, M_{k}$,

$$
S \otimes_{R}\left(M_{1} \otimes_{R} \cdots \otimes_{R} M_{k}\right) \cong\left(S \otimes_{R} M_{1}\right) \otimes_{S} \cdots \otimes_{S}\left(S \otimes M_{k}\right)
$$

as $S$-modules, where $s \otimes_{S}\left(m_{1} \otimes_{R} \cdots \otimes_{R} m_{k}\right) \mapsto s\left(\left(1 \otimes_{R} m_{1}\right) \otimes_{S} \cdots \otimes_{S}\left(1 \otimes_{R} m_{k}\right)\right)$. In particular, $S \otimes_{R}\left(M^{\otimes_{R} k}\right) \cong\left(S \otimes_{R} M\right)^{\otimes_{S} k}$ as $S$-modules.
Proof. Induct on $k$.
Example 6.28. For a real vector space $V, \mathbf{C} \otimes_{\mathbf{R}}\left(V \otimes_{\mathbf{R}} V\right) \cong\left(\mathbf{C} \otimes_{\mathbf{R}} V\right) \otimes_{\mathbf{C}}\left(\mathbf{C} \otimes_{\mathbf{R}} V\right)$. The middle tensor product sign on the right is over $\mathbf{C}$, not $\mathbf{R}$. Note that $\mathbf{C} \otimes_{\mathbf{R}}\left(V \otimes_{\mathbf{R}} V\right) \neq$ $\left(\mathbf{C} \otimes_{\mathbf{R}} V\right) \otimes_{\mathbf{R}}\left(\mathbf{C} \otimes_{\mathbf{R}} V\right)$ when $V \neq 0$, as the two sides have different dimensions over $\mathbf{R}$ (what are they?).

The base extension $M \rightsquigarrow S \otimes_{R} M$ turns $R$-modules into $S$-modules in a systematic way. So does $M \rightsquigarrow M \otimes_{R} S$, and this is essentially the same construction. This suggests there should be a universal mapping problem about $R$-modules and $S$-modules that is solved by base extension, and there is: it is the universal device for turning each $R$-linear map from $M$ to an $S$-module into an $S$-linear map of $S$-modules.

Theorem 6.29. Let $M$ be an $R$-module. For every $S$-module $N$ and $R$-linear map $\varphi: M \rightarrow$ $N$, there is a unique $S$-linear map $\varphi^{S}: S \otimes_{R} M \rightarrow N$ such that the diagram

commutes.
This says the single $R$-linear map $M \rightarrow S \otimes_{R} M$ from $M$ to an $S$-module explains all other $R$-linear maps from $M$ to $S$-modules using composition of it with $S$-linear maps from $S \otimes_{R} M$ to $S$-modules.

Proof. Assume there is such an $S$-linear map $\varphi^{S}$. We will derive a formula for it on elementary tensors:

$$
\varphi^{S}(s \otimes m)=\varphi^{S}(s(1 \otimes m))=s \varphi^{S}(1 \otimes m)=s \varphi(m) .
$$

This shows $\varphi^{S}$ is unique if it exists.
To prove existence, consider the function $S \times M \rightarrow N$ by $(s, m) \mapsto s \varphi(m)$. This is $R$ bilinear (check!), so there is an $R$-linear map $\varphi^{S}: S \otimes_{R} M \rightarrow N$ such that $\varphi^{S}(s \otimes m)=s \varphi(m)$. Using the $S$-module structure on $S \otimes_{R} M, \varphi^{S}$ is $S$-linear.

For $\varphi$ in $\operatorname{Hom}_{R}(M, N), \varphi^{S}$ is in $\operatorname{Hom}_{S}\left(S \otimes_{R} M, N\right)$. Because $\varphi^{S}(1 \otimes m)=\varphi(m)$, we can recover $\varphi$ from $\varphi^{S}$. But even more is true.
Theorem 6.30. Let $M$ be an $R$-module and $N$ be an $S$-module. The function $\varphi \mapsto \varphi^{S}$ is an $S$-module isomorphism $\operatorname{Hom}_{R}(M, N) \rightarrow \operatorname{Hom}_{S}\left(S \otimes_{R} M, N\right)$.

How is $\operatorname{Hom}_{R}(M, N)$ an $S$-module? Values of these functions are in $N$, which is an $S$ module, so $S$ turns scales each function $M \rightarrow N$ to a new function $M \rightarrow N$ by just scaling the values.

Proof. For $\varphi$ and $\varphi^{\prime}$ in $\operatorname{Hom}_{R}(M, N),\left(\varphi+\varphi^{\prime}\right)^{S}=\varphi^{S}+\varphi^{\prime S}$ and $(s \varphi)^{S}=s \varphi^{S}$ by checking both sides are equal on all elementary tensors in $S \otimes_{R} M$. Therefore $\varphi \mapsto \varphi^{S}$ is $S$-linear. Its injectivity is discussed above ( $\varphi^{S}$ determines $\varphi$ ).

For surjectivity, let $h: S \otimes_{R} M \rightarrow N$ be $S$-linear. Set $\varphi: M \rightarrow N$ by $\varphi(m)=h(1 \otimes m)$. Then $\varphi$ is $R$-linear and $\varphi^{S}(s \otimes m)=s \varphi(m)=s h(1 \otimes m)=h(s(1 \otimes m))=h(s \otimes m)$, so $h=\varphi^{S}$ since both are additive and are equal at all elementary tensors.

The $S$-module isomorphism

$$
\begin{equation*}
\operatorname{Hom}_{R}(M, N) \cong \operatorname{Hom}_{S}\left(S \otimes_{R} M, N\right) \tag{6.4}
\end{equation*}
$$

should be thought of as analogous to the $R$-module isomorphism

$$
\begin{equation*}
\operatorname{Hom}_{R}\left(M, \operatorname{Hom}_{R}(N, P)\right) \cong \operatorname{Hom}_{R}\left(M \otimes_{R} N, P\right) \tag{6.5}
\end{equation*}
$$

from Theorem 5.7, where $-\otimes_{R} N$ is left adjoint to $\operatorname{Hom}_{R}(N,-)$. (In (6.5), $N$ and $P$ are $R$-modules, not $S$-modules! We're using the same notation as in Theorem 5.7.) If we look at (6.4), we see $S \otimes_{R}$ - is applied to $M$ on the right but nothing special is applied to $N$ on the left. Yet there is something different about $N$ on the two sides of (6.4). It is an $S$-module on the right side of (6.4), but on the left side it is being treated as an $R$-module (restriction of scalars). That changes $N$, but we have introduced no notation to reflect this. We still just write it as $N$. Let's now write $\operatorname{Res}_{S / R}(N)$ to denote $N$ as an $R$-module. It is
the same underlying additive group as $N$, but the scalars are now taken from $R$ with the rule $r n=f(r) n$. The appearance of (6.4) now looks like this:

$$
\begin{equation*}
\operatorname{Hom}_{R}\left(M, \operatorname{Res}_{S / R}(N)\right) \cong \operatorname{Hom}_{S}\left(S \otimes_{R} M, N\right) \tag{6.6}
\end{equation*}
$$

So extension of scalars (from $R$-modules to $S$-modules) is left adjoint to restriction of scalars (from $S$-modules to $R$-modules) in a similar way that $-\otimes_{R} M$ is left adjoint to $\operatorname{Hom}_{R}(M,-)$.

Using this new notation for restriction of scalars, the important $S$-module isomorphism (6.3) can be written more explicitly as

$$
M \otimes_{R} \operatorname{Res}_{S / R}(N) \cong\left(S \otimes_{R} M\right) \otimes_{S} N,
$$

Theorem 6.31. Let $M$ be an $R$-module and $N$ and $P$ be $S$-modules. There is an $S$-module isomorphism

$$
\operatorname{Hom}_{S}\left(M \otimes_{R} N, P\right) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Res}_{S / R}\left(\operatorname{Hom}_{S}(N, P)\right)\right)
$$

Example 6.32. Taking $N=S$, so $M \otimes_{R} N=M \otimes_{R} S \cong S \otimes_{R} M$,

$$
\operatorname{Hom}_{S}\left(S \otimes_{R} M, P\right) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Res}_{S / R}(P)\right)
$$

since $\operatorname{Hom}_{S}(S, P) \cong P$. We have recovered $S \otimes_{R}$ - being left adjoint to $\operatorname{Res}_{S / R}$.
Example 6.33. Taking $S=R$, so $N$ and $P$ are now $R$-modules,

$$
\operatorname{Hom}_{R}\left(M \otimes_{R} N, P\right) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Hom}_{R}(N, P)\right)
$$

We have recovered $-\otimes_{R} N$ being left adjoint to $\operatorname{Hom}_{R}(N,-)$ for $R$-modules $N$.
These two consequences of Theorem 6.31 are results we have already seen, and in fact we are going to use them in the proof, so they are together equivalent to Theorem 6.31.

Proof. Since $M \otimes_{R} N \cong\left(S \otimes_{R} M\right) \otimes_{S} N$ as $S$-modules,

$$
\operatorname{Hom}_{S}\left(M \otimes_{R} N, P\right) \cong \operatorname{Hom}_{S}\left(\left(S \otimes_{R} M\right) \otimes_{S} N, P\right)
$$

Since $-\otimes_{S} N$ is left adjoint to $\operatorname{Hom}_{S}(N,-)$,

$$
\operatorname{Hom}_{S}\left(\left(S \otimes_{R} M\right) \otimes_{S} N, P\right) \cong \operatorname{Hom}_{S}\left(S \otimes_{R} M, \operatorname{Hom}_{S}(N, P)\right)
$$

Since $S \otimes_{R}$ - is left adjoint to $\operatorname{Res}_{S / R}$,

$$
\operatorname{Hom}_{S}\left(S \otimes_{R} M, \operatorname{Hom}_{S}(N, P)\right) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Res}_{S / R}\left(\operatorname{Hom}_{S}(N, P)\right)\right)
$$

Combining these three isomorphisms,

$$
\operatorname{Hom}_{S}\left(M \otimes_{R} N, P\right) \cong \operatorname{Hom}_{R}\left(M, \operatorname{Res}_{S / R}\left(\operatorname{Hom}_{S}(N, P)\right)\right)
$$

Here is an explicit (overall) isomorphism. If $\varphi: M \otimes_{R} N \rightarrow P$ is $S$-linear there is an $R$-linear $\operatorname{map} L_{\varphi}: M \rightarrow \operatorname{Hom}_{S}(N, P)$ by $L_{\varphi}(m)=\varphi(m \otimes(-))$. If $\psi: M \rightarrow \operatorname{Hom}_{S}(N, P)$ is $R$-linear then $M \times N \rightarrow P$ by $(m, n) \mapsto \psi(m)(n)$ is $R$-bilinear and $\psi(m)(s n)=s \psi(m)(n)$, so the corresponding $R$-linear map $\widetilde{L}_{\psi}: M \otimes_{R} N \rightarrow P$ where $\widetilde{L}_{\psi}(m \otimes n)=\psi(m)(n)$ is $S$-linear. The functions $\varphi \mapsto L_{\varphi}$ and $\psi \mapsto \widetilde{L}_{\psi}$ are $S$-linear and are inverses.

## 7. Tensors in Physics

In physics and engineering, tensors are often defined not in terms of multilinearity, but by the way tensors look in different coordinate systems. Here is a definition of a tensor that can be found (more or less) in many physics textbooks. Let $V$ be a vector space ${ }^{25}$ with dimension $n \geq 1$. A tensor of rank 0 on $V$ is a scalar. For $k \geq 1$, a contravariant tensor of rank $k^{26}$ (on $V$ ) is an object T with $n^{k}$ components in every coordinate system of $V$ such that if $\left\{T^{i_{1}, \ldots, i_{k}}\right\}_{1 \leq i_{1}, \ldots, i_{k} \leq n}$ and $\left\{\widetilde{T}^{i_{1}, \ldots, i_{k}}\right\}_{1 \leq i_{1}, \ldots, i_{k} \leq n}$ are the components of T in two coordinate systems of $V$ then

$$
\begin{equation*}
\widetilde{T}^{i_{1}, \ldots, i_{k}}=\sum_{1 \leq j_{1}, \ldots, j_{k} \leq n} T^{j_{1}, \ldots, j_{k}} a_{i_{1} j_{1}} \cdots a_{i_{k} j_{k}}, \tag{7.1}
\end{equation*}
$$

where $\left(a_{i j}\right)$ is the matrix is the matrix expressing the first coordinate system of $V$ in terms of the second. In short, a contravariant tensor of rank $k$ is a "quantity that transforms by the rule (7.1)."

What is being described here, with components, is just an element of $V^{\otimes k}$. To see this, note that a coordinate system means a choice of a basis of $V$. For each basis ${ }^{27}\left\{e_{1}, \ldots, e_{n}\right\}$ of $V$, in which T has components $\left\{T^{i_{1}, \ldots, i_{k}}\right\}_{1 \leq i_{1}, \ldots, i_{k} \leq n}$, make these numbers the coefficients of the basis $\left\{e_{i_{1}} \otimes \cdots \otimes e_{i_{k}}\right\}$ of $V^{\otimes k}$ :

$$
\sum_{1 \leq i_{1}, \ldots, i_{k} \leq n} T^{i_{1}, \ldots, i_{k}} e_{i_{1}} \otimes \cdots \otimes e_{i_{k}}
$$

This belongs to $V^{\otimes k}$. Let's express this sum in terms of a second basis ("coordinate system") $\left\{f_{1}, \ldots, f_{n}\right\}$ of $V$. Writing $e_{j}=\sum_{i=1}^{n} a_{i j} f_{i}$, the above sum equals, after a notational change,

$$
\begin{aligned}
& \sum_{1 \leq j_{1}, \ldots, j_{k} \leq n} T^{j_{1}, \ldots, j_{k}} e_{j_{1}} \otimes \cdots \otimes e_{j_{k}} \\
= & \sum_{1 \leq j_{1}, \ldots, j_{k} \leq n} T^{j_{1}, \ldots, j_{k}}\left(\sum_{i_{1}=1}^{n} a_{i_{1} j_{1}} f_{i_{1}}\right) \otimes \cdots \otimes\left(\sum_{i_{k}=1}^{n} a_{i_{k} j_{k}} f_{i_{k}}\right) \\
= & \sum_{1 \leq i_{1}, \ldots, i_{k} \leq n}\left(\sum_{1 \leq j_{1}, \ldots, j_{k} \leq n} T^{j_{1}, \ldots, j_{k}} a_{i_{1} j_{1}} \cdots a_{i_{k} j_{k}}\right) f_{i_{1}} \otimes \cdots \otimes f_{i_{k}} \\
= & \sum_{1 \leq i_{1}, \ldots, i_{k} \leq n} \widetilde{T}^{i_{1}, \ldots, i_{k}} f_{i_{1}} \otimes \cdots \otimes f_{i_{k}} \quad \text { by }(7.1) .
\end{aligned}
$$

So in physics, the components of a contravariant rank $k$ tensor on $V$ are the coefficients of an element of $V^{\otimes k}$ in some basis ${ }^{28}$ of $V^{\otimes k}$. In physics, $\operatorname{dim} V$ is usually 3 or 4.

Switching from tensor powers of $V$ to tensor powers of its dual space $V^{\vee}$, we now want to compare the representations of an element of $\left(V^{\vee}\right)^{\otimes \ell}$ in coordinate systems built from the two dual bases $e_{1}^{\vee}, \ldots, e_{n}^{\vee}$ and $f_{1}^{\vee}, \ldots, f_{n}^{\vee}$ of $V^{\vee}$. The formula we find will be similar to (7.1), but with a crucial change.

[^19]To align calculations with how they're done in physics and differential geometry, from now on write the dual bases of $\left\{e_{1}, \ldots, e_{n}\right\}$ and $\left\{f_{1}, \ldots, f_{n}\right\}$ as $\left\{e^{1}, \ldots, e^{n}\right\}$ and $\left\{f^{1}, \ldots, f^{n}\right\}$, not $\left\{e_{1}^{\vee}, \ldots, e_{n}^{\vee}\right\}$ and $\left\{f_{1}^{\vee}, \ldots, f_{n}^{\vee}\right\}$. So $e^{i}\left(e_{j}\right)=f^{i}\left(f_{j}\right)=\delta_{i j}$ for all $i$ and $j$.

For a basis $\left\{e_{1}, \ldots, e_{n}\right\}$ of $V$ and its dual basis $\left\{e^{1}, \ldots, e^{n}\right\}$ in $V^{\vee}$, general elements of $V$ and $V^{\vee}$ are written as $\sum_{i=1}^{n} c^{i} e_{i}$ and $\sum_{i=1}^{n} c_{i} e^{i}$, respectively. A basis of $V$ always has lower indices and its coefficients have upper indices, while a basis of $V^{\vee}$ always has upper indices. and its coefficients have lower indices. See the table below.

| Space | Basis | Coeff. | Element |
| :---: | :---: | :---: | :---: |
| $V$ | $e_{i}$ | $c^{i}$ | $\sum c^{i} e_{i}$ |
| $V^{\vee}$ | $e^{i}$ | $c_{i}$ | $\sum c_{i} e^{i}$ |

The convention of lower indices for a basis of $V$ and for coefficients of a basis in $V^{\vee}$ and upper indices for a basis of $V^{\vee}$ and for coefficients of a basis in $V$ is consistent since the coefficients $a^{i}$ of the vector $\sum_{i=1}^{n} a^{i} e_{i}$ in $V$ are the values of $e^{1}, \ldots, e^{n}$ on this vector: coefficients of a basis are coordinate functions, and coordinate functions of a basis of $V$ lie in $V^{\vee}$ while, by duality, coordinate functions of a basis of $V^{\vee}$ lie in $\left(V^{\vee}\right)^{\vee} \cong V$.

Pick a mathematician's tensor $\mathrm{T} \in\left(V^{\vee}\right)^{\otimes \ell}$ and write it in the basis $\left\{e^{i_{1}} \otimes \cdots \otimes e^{i \ell}\right\}$ as

$$
\begin{equation*}
\mathrm{T}=\sum_{1 \leq i_{1}, \ldots, i_{\ell} \leq n} T_{i_{1}, \ldots, i_{\ell}} e^{i_{1}} \otimes \cdots \otimes e^{i_{\ell}} \tag{7.2}
\end{equation*}
$$

where the coefficients have lower indices, not upper indices, to be consistent with the idea that this is a dual object (lies in a tensor power of $V^{\vee}$ ). To express T in terms of the second basis $\left\{f^{i_{1}} \otimes \cdots \otimes f^{i_{\ell}}\right\}$ of $\left(V^{\vee}\right)^{\otimes \ell}$, we want to express the $e^{j}$ 's in terms of the $f^{i}$ 's in $V^{\vee}$.

We already wrote $e_{j}=\sum_{i=1}^{n} a_{i j} f_{i}$ in $V$ for all $j$, and it turns out that

$$
\begin{equation*}
e_{j}=\sum_{i=1}^{n} a_{i j} f_{i} \text { for all } j \Longrightarrow f^{j}=\sum_{i=1}^{n} a_{j i} e^{i} \text { for all } j \tag{7.3}
\end{equation*}
$$

Indeed, the coefficient of $e^{i}$ is $f^{j}\left(e_{i}\right)=f^{j}\left(\sum_{k} a_{k i} f_{k}\right)=a_{j i}$. We see transposed matrix entries $\left(a_{j i}\right)$ on the right side of (7.3) in an essential way: $j$ in (7.3) is the second index of $a_{i j}$ and the first index of $a_{j i}$. It is a fact of life that passing to the dual space involves a transpose. Alas, (7.3) gives a change of basis formula in $V^{\vee}$ for $f^{j}$ 's in terms of $e^{i}$ 's, which is not the direction we need to transform the right side of (7.2) to a sum involving $f^{i}$ 's: we want the $e^{j}$ 's in terms of the $f^{i}$ 's, not the $f^{j}$ 's in terms of the $e^{i}$ 's. So we need an inverse on top of the transposing.

Writing the inverse of the matrix $\left(a_{i j}\right)$ as $\left(a^{i j}\right)$, the following table summarizes how a change of basis matrix changes to describe a related change of basis.

| Space | Start | End | Matrix |
| :---: | :---: | :---: | :---: |
| $V$ | $f_{1}, \ldots, f_{n}$ | $e_{1}, \ldots, e_{n}$ | $\left(a_{i j}\right)-$ definition |
| $V$ | $e_{1}, \ldots, e_{n}$ | $f_{1}, \ldots, f_{n}$ | $\left(a^{i j}\right)=\left(a_{i j}\right)^{-1}$ |
| $V^{\vee}$ | $e^{1}, \ldots, e^{n}$ | $f^{1}, \ldots, f^{n}$ | $\left(a_{j i}\right)=\left(a_{i j}\right)^{\top}$ |
| $V^{\vee}$ | $f^{1}, \ldots, f^{n}$ | $e^{1}, \ldots, e^{n}$ | $\left(a^{j i}\right)=\left(a^{i j}\right)^{\top}$ |

The third row of the table is (7.3) and the second and fourth rows of the table say

$$
\begin{equation*}
e_{j}=\sum_{i=1}^{n} a_{i j} f_{i} \text { for all } j \Longrightarrow f_{j}=\sum_{i=1}^{n} a^{i j} e_{i}, \text { and } e^{j}=\sum_{i=1}^{n} a^{j i} f^{i} \text { for all } j . \tag{7.4}
\end{equation*}
$$

Example 7.1. Let $\operatorname{dim}(V)=2$ with bases $\left\{e_{1}, e_{2}\right\}$ and $\left\{f_{1}, f_{2}\right\}$. Suppose that

$$
e_{1}=f_{1}+2 f_{2} \text { and } e_{2}=3 f_{2} .
$$

It follows by simple algebra that

$$
f_{1}=e_{1}-\frac{2}{3} e_{2} \quad \text { and } \quad f_{2}=\frac{1}{3} e_{2} .
$$

Write these as $e_{j}=\sum_{i=1}^{2} a_{i j} f_{i}$ and $f_{j}=\sum_{i=1}^{2} a^{i j} e_{i}$ for

$$
\left(a_{i j}\right)=\left(\begin{array}{ll}
1 & 0  \tag{7.5}\\
2 & 3
\end{array}\right) \quad \text { and } \quad\left(a^{i j}\right)=\left(\begin{array}{cc}
1 & 0 \\
-2 / 3 & 1 / 3
\end{array}\right)
$$

which are inverses.
In $V^{\vee}$, to write $\left\{f^{1}, f^{2}\right\}$ in terms of $\left\{e^{1}, e^{2}\right\}$ set $f^{1}=a e^{1}+b e^{2}$. Evaluating both sides at $f_{1}$ and $f_{2}$ we have $1=a e^{1}\left(f_{1}\right)+b e^{2}\left(f_{1}\right)=a+b(-2 / 3)$ and $0=a e^{1}\left(f_{2}\right)+b e^{2}\left(f_{2}\right)=b(1 / 3)$. Thus $b=0$ and $a=1$, so $f^{1}=e^{1}$. Similarly, $f^{2}=2 e^{1}+3 e^{2}$ and we can solve for $e^{1}$ and $e^{2}$ :

$$
f^{1}=e^{1} \text { and } f^{2}=2 e^{1}+3 e^{2} \Longrightarrow e^{1}=f^{1} \text { and } e^{2}=-\frac{2}{3} f^{1}+\frac{1}{3} f^{2}
$$

Then $f^{j}=\sum_{i=1}^{2} a_{j i} e^{i}$ and $e^{j}=\sum_{i=1}^{2} a^{j i} f^{i}$, with coefficients forming transposed matrices to (7.5).

The change of basis we need for (7.2) is $e^{j}$ 's in terms of $f^{i}$ 's, so isolate that part of (7.4):

$$
\begin{equation*}
e_{j}=\sum_{i=1}^{n} a_{i j} f_{i} \text { for all } j \Longrightarrow e^{j}=\sum_{i=1}^{n} a^{j i} f^{i} \text { for all } j \tag{7.6}
\end{equation*}
$$

As a reminder, $\left(a^{j i}\right)$ is the transpose of the inverse of the matrix $\left(a_{i j}\right)$.
Returning to (7.2),

$$
\begin{align*}
\mathrm{T} & =\sum_{1 \leq j_{1}, \ldots, j_{\ell} \leq n} T_{j_{1}, \ldots, j_{\ell}} e^{j_{1}} \otimes \cdots \otimes e^{j_{\ell}} \\
& =\sum_{1 \leq j_{1}, \ldots, j_{\ell} \leq n} T_{j_{1}, \ldots, j_{\ell}}\left(\sum_{i_{1}=1}^{n} a^{j_{1} i_{1}} f^{i_{1}}\right) \otimes \cdots \otimes\left(\sum_{i_{\ell}=1}^{n} a^{j_{\ell} i_{\ell}} f^{i_{\ell}}\right) \text { by }(7.6)  \tag{7.6}\\
& =\sum_{1 \leq i_{1}, \ldots, i_{\ell} \leq n}\left(\sum_{1 \leq j_{1}, \ldots, j_{\ell} \leq n} T_{j_{1}, \ldots, j_{\ell}} a^{j_{1} i_{1}} \cdots a^{j_{\ell} i_{\ell}}\right) f^{i_{1}} \otimes \cdots \otimes f^{i_{\ell}} .
\end{align*}
$$

The component-based approach to $\left(V^{\vee}\right)^{\otimes \ell}$ is based on this calculation. A "quantity with $n^{k}$ components that transforms by the rule"

$$
\begin{equation*}
\widetilde{T}_{i_{1}, \ldots, i_{\ell}}=\sum_{1 \leq j_{1}, \ldots, j_{\ell} \leq n} T_{j_{1}, \ldots, j_{\ell}} a^{j_{1} i_{1}} \cdots a^{j_{\ell} i_{\ell}} \tag{7.7}
\end{equation*}
$$

when passing from the basis $\left\{e^{1}, \ldots, e^{n}\right\}$ to the basis $\left\{f^{1}, \ldots, f^{n}\right\}$ of $V^{\vee}$, is called a covariant tensor of rank $\ell$. This is just an element of $\left(V^{\vee}\right)^{\otimes \ell}$, and (7.7) explains operationally how different coordinate representations of this tensor are related to one another.

The rules (7.1) for components in $V^{\otimes k}$ and (7.7) for components in $\left(V^{\vee}\right)^{\otimes \ell}$ are different, and not just on account of the convention about indices being upper on tensor components in (7.1) and lower on tensor components in (7.7). If we place (7.1) and (7.7) side by side
and, to avoid being distracted by tensor index notational conventions, we temporarily make all tensor-component indices lower and give the tensor components the same number of indices $\left(\ell=k\right.$, so we are in $V^{\otimes k}$ and $\left.\left(V^{\vee}\right)^{\otimes k}\right)$, we obtain this:

$$
\widetilde{T}_{i_{1}, \ldots, i_{k}}=\sum_{1 \leq j_{1}, \ldots, j_{k} \leq n} T_{j_{1}, \ldots, j_{k}} a_{i_{1} j_{1}} \cdots a_{i_{k} j_{k}}, \quad \widetilde{T}_{i_{1}, \ldots, i_{k}}=\sum_{1 \leq j_{1}, \ldots, j_{k} \leq n} T_{j_{1}, \ldots, j_{k}} a^{j_{1} i_{1}} \cdots a^{j_{k} i_{k}}
$$

We did not lower the indices of $a^{j i}$ in the second sum because its indices reflect something serious: $\left(a_{i j}\right)$ is the matrix expressing a change of coordinates in $V$ and $\left(a^{j i}\right)$ is the matrix expressing the dual change of coordinates in $V^{\vee}$ in the same direction (see (7.6)). The use of $a_{i j}$ or $a^{j i}$ is the difference between the transformation rules in tensor powers of $V$ and tensor powers of $V^{\vee}$. Both of the transformation rules involve a multilinear change of coordinates (as evidenced by the multiple products in the sums), but in the first rule the summation indices appear in the multipliers $a_{i_{r} j_{r}}$ as the second index, while in the second rule the summation indices appear in the multipliers $a^{j_{r} i_{r}}$ as the first index. This swap happens because physicists always start a change of basis in $V$, and passing to the effect in $V^{\vee}$ necessitates a transpose (and inverse). The reason for systematically using upper indices on tensor components satisfying (7.1) and lower indices on tensor components satisfying (7.7) is to know at a glance (with experience) what type of transformation rule the tensor components will satisfy under a change in coordinates.

Here is some terminology about tensors that is used by physicists.

- A contravariant tensor of rank $k$, which is an indexed quantity $T^{i_{1} \ldots i_{k}}$ that transforms by (7.1), is also called a tensor of rank $k$ with upper indices (easier to remember!).
- A covariant tensor of rank $\ell$, which is an indexed quantity $T_{j_{1} \ldots j_{\ell}}$ that transforms by (7.7), is also called a tensor of rank $\ell$ with lower indices.
- An indexed quantity $T_{j_{1} \ldots j_{\ell}}^{i_{1} \ldots i_{k}}$ that transforms by the rule

$$
\begin{equation*}
\widetilde{T}_{j_{1} \ldots j_{\ell}}^{i_{1} \ldots i_{k}}=\sum_{\substack{1 \leq p_{1}, \ldots, p_{k} \leq n \\ 1 \leq q_{1}, \ldots, q_{\ell} \leq n}} T_{q_{1} \ldots q_{\ell}}^{p_{1} \ldots p_{k}} a_{i_{1} p_{1}} \cdots a_{i_{k} p_{k}} a^{q_{1} j_{1}} \cdots a^{q_{\ell} j_{\ell}} \tag{7.8}
\end{equation*}
$$

is called a tensor of type $(k, \ell)$ and rank $k+\ell$. This "quantity" is just an element of $V^{\otimes k} \otimes\left(V^{\vee}\right)^{\otimes \ell}$ written in terms of elementary tensor product bases produced from a basis of $V$ (check!). For instance, elements of $V \otimes V, V \otimes V^{\vee}$, and $V^{\vee} \otimes V^{\vee}$ are rank 2 tensors. An element of $V^{\otimes 2} \otimes V^{\vee}$ has rank 3 and its components are $T_{j}^{i_{1} i_{2}}$.

If we permute the order of the spaces in the tensor product from the conventional "first every $V$, then every $V^{\vee}$," then the indexing rule on tensors needs to be adapted: $V \otimes V^{\vee} \otimes V$ is not the same space as $V \otimes V \otimes V^{\vee}$, so we shouldn't write its tensor components as $T_{j}^{i_{1} i_{2}}$. Write them as $T^{i_{1}}{ }_{j}{ }_{2}$, so that as we read indices from left to right we see each index in the order its corresponding space appears in $V \otimes V^{\vee} \otimes V$ : upper indices for $V$ and lower indices for $V^{\vee}$.

Example 7.2. To compare transformation rules for rank 2 tensors in $V^{\otimes 2}$ (type (2,0)), $\left(V^{\vee}\right)^{\otimes 2}$ (type $\left.(0,2)\right)$, and $V \otimes V^{\vee}$ (type $\left.(1,1)\right)$, let bases $\left\{e_{1}, \ldots, e_{n}\right\}$ and $\left\{f_{1}, \ldots, f_{n}\right\}$ of $V$ be related by numbers $a_{i j}$ as in (7.3) and (7.4): $e_{j}=\sum_{i} a_{i j} f_{i}$ for all $j$.

Case 1: (2,0)-tensors. By (7.1), in $V^{\otimes 2}$ we have $\sum_{j_{1}, j_{2}} T^{j_{1} j_{2}} e_{j_{1}} \otimes e_{j_{2}}=\sum_{i_{1}, i_{2}} \widetilde{T}^{i_{1} i_{2}} f_{i_{1}} \otimes f_{i_{2}}$ where

$$
\begin{equation*}
\widetilde{T}^{i_{1} i_{2}}=\sum_{j_{1}, j_{2}} T^{j_{1} j_{2}} a_{i_{1} j_{1}} a_{i_{2} j_{2}} \tag{7.9}
\end{equation*}
$$

Case 2: $(0,2)$-tensors. In $\left(V^{\vee}\right)^{\otimes 2}, \sum_{j_{1}, j_{2}} T_{j_{1} j_{2}} e^{j_{1}} \otimes e^{j_{2}}=\sum_{i_{1}, i_{2}} \widetilde{T}_{i_{1} i_{2}} f^{i_{1}} \otimes f^{i_{2}}$ where

$$
\begin{equation*}
\widetilde{T}_{i_{1} i_{2}}=\sum_{j_{1}, j_{2}} T_{j_{1} j_{2}} a^{j_{1} i_{1}} a^{j_{2} i_{2}} \tag{7.10}
\end{equation*}
$$

with the matrix $\left(a^{i j}\right)$ being the inverse of $\left(a_{i j}\right)$, so $e^{j}=\sum_{i} a^{j i} f^{i}$ for all $j$ by (7.4).
Case 3: (1,1)-tensors. In $V \otimes V^{\vee}, \sum_{j_{1}, j_{2}} T_{j_{2}}^{j_{1}} e_{j_{1}} \otimes e^{j_{2}}=\sum_{i_{1}, i_{2}} \widetilde{T}_{i_{2}}^{i_{1}} f_{i_{1}} \otimes f^{i_{2}}$ where

$$
\begin{equation*}
\widetilde{T}_{i_{2}}^{i_{1}}=\sum_{j_{1}, j_{2}} T_{j_{2}}^{j_{1}} a_{i_{1} j_{1}} a^{j_{2} i_{2}} \tag{7.11}
\end{equation*}
$$

The $n^{2}$ components of such tensors relative to the basis $\left\{e_{1}, \ldots, e_{n}\right\}$ can be put into an $n \times n$ matrix $\left(T^{i j}\right),\left(T_{i j}\right)$, or $\left(T_{j}^{i}\right)$. We can rewrite (7.9), (7.10), and (7.11) so the sums on the right look like formulas from multiplying 3 matrices:

$$
\widetilde{T}^{i_{1} i_{2}}=\sum_{j_{1}, j_{2}} a_{i_{1} j_{1}} T^{j_{1} j_{2}} a_{i_{2} j_{2}}, \quad \widetilde{T}_{i_{1} i_{2}}=\sum_{j_{1}, j_{2}} a^{j_{1} i_{1}} T_{j_{1} j_{2}} a^{j_{2} i_{2}}, \quad \widetilde{T}_{i_{2}}^{i_{1}}=\sum_{j_{1}, j_{2}} a_{i_{1} j_{1}} T_{j_{2}}^{j_{1}} a^{j_{2} i_{2}}
$$

By how indices in these sums repeat, the matrix of components of a tensor of rank 2 transform as indicated in the table below.

| Type | Transformation Rule |
| :---: | :---: |
| $(2,0)$ | $\left(\widetilde{T}^{i j}\right)=\left(a_{i j}\right)\left(T^{i j}\right)\left(a_{i j}\right)^{\top}$ |
| $(0,2)$ | $\left(\widetilde{T}_{i j}\right)=\left(a^{i j}\right)^{\top}\left(T_{i j}\right)\left(a^{i j}\right)$ |
| $(1,1)$ | $\left(\widetilde{T}_{j}^{i}\right)=\left(a_{i j}\right)\left(T_{j}^{i}\right)\left(a_{i j}\right)^{-1}$ |

The $(0,2)$ case is how the matrix representation of a bilinear form changes after a change of basis and the $(1,1)$ case is how the matrix representation of a linear map of a vector space to itself changes after a change of basis. This is why a bilinear form (such as an inner product or a spacetime metric in relativity) is a ( 0,2 )-tensor and a linear map of a vector space to itself is a (1,1)-tensor. We saw the interpretation of (1,1)-tensors as linear maps before, without coordinates: from Example $5.11, V \otimes V^{\vee} \cong \operatorname{Hom}(V, V)$. Warning: the "rank" of a linear map $V \rightarrow V$ (the dimension of its image) has nothing to do with its "rank" in the above sense as a tensor in $V \otimes V^{\vee}$, which is always 2.

While $V$ and $V^{\vee}$ are not literally the same, they are isomorphic. If we fix an isomorphism between them and use it everywhere to replace $V^{\vee}$ with $V$ then the different spaces of rank 2 tensors can all be made to look like $V^{\otimes 2}$, a process called "raising indices" since it turns $T_{i j}$ and $T_{j}^{i}$ into $T^{i j}$. This is done very often in geometry and physics since $\mathbf{R}^{n}$ is treated as isomorphic to its dual space using the standard dot product to identify $\left(\mathbf{R}^{n}\right)^{\vee}$ with $\mathbf{R}^{n}$.

Let's compare how the mathematician and physicist think about a tensor:

- (Mathematician) Tensors belongs to a tensor space, which is a module - or more often in geometry a vector space - defined by a multilinear universal mapping property.
- (Physicist) "Tensors are systems of components organized by one or more indices that transform according to specific rules under a set of transformations." 29
In a tensor product of vector spaces, mathematicians and physicists can check two tensors $t$ and $t^{\prime}$ are equal in the same way: check $t$ and $t^{\prime}$ have the same components in one coordinate system. (Physicists don't deal with modules that aren't vector spaces, so they always have bases available.) The reason mathematicians and physicists consider this to be

[^20]a sufficient test of equality is not the same. The mathematician thinks about the condition $t=t^{\prime}$ in a coordinate-free way and knows that to check $t=t^{\prime}$ it suffices to check $t$ and $t^{\prime}$ have the same coordinates in one basis. The physicist considers the condition $t=t^{\prime}$ to mean (by definition!) that the components of $t$ and $t^{\prime}$ match in all coordinate systems, and the multilinear transformation rule (7.7), or (7.8), on tensors implies that if the components of $t$ and $t^{\prime}$ are equal in one coordinate system then they are equal in every coordinate system. That's why the physicist is content to look in just one coordinate system.

Consider Einstein's description of tensors in a paper on general relativity [4, p. 157]:30
Let certain things ("tensors") be defined with respect to any system of coordinates by a number of functions of the co-ordinates, called the "components" of the tensor. There are then certain rules by which these components can be calculated for a new system of co-ordinates, if they are known for the original system of co-ordinates, and if the transformation connecting the two systems is known. The things hereafter called tensors are further characterized by the fact that the equations of transformation for their components are linear and homogeneous. Accordingly, all the components in the new system vanish, if they all vanish in the original system.
Einstein's "linear and homogeneous" equations is what we call "multilinear" equations.
An operation on tensors (like the flip $v \otimes w \mapsto w \otimes v$ on $V^{\otimes 2}$ ) is checked to be welldefined by the mathematician and physicist in different ways. The mathematician checks the operation respects the universal mapping property that defines tensor products, while the physicist checks the explicit formula for the operation on elementary tensors changes in different coordinate systems by the tensor transformation rule (like (7.1)). The physicist would say an operation on tensors makes sense because it transforms "tensorially" (like a tensor), which in more expansive terms means that the formulas for the operation in two different coordinate systems are related by a multilinear change of variables. However, textbooks on classical mechanics and quantum mechanics that treat tensors don't seem to use the word "multilinear," even though that word describes exactly what is going on. Instead, these textbooks nearly always say that a tensor's components transform by a "definite rule" or a "specific rule," which doesn't seem to have an actual meaning; isn't every computational rule a specific rule? Graduate textbooks on general relativity are an exception to this habit: [3], [16], and [26] all define tensors in terms of multilinearity. ${ }^{31}$

Mathematicians and students in mathematics may be baffled about how physicists can think about tensors just in terms of components. Conceptual definitions in mathematics are very nice, but the ugly component viewpoint of tensors is not only crucial to understanding how tensors show up in physics, but they are also how tensors were handled in mathematics through the first part of the 20th century ${ }^{32}$. Hassler Whitney, who we mentioned at the end of Section 3 as the first person to extend tensor products from vector spaces to abelian groups, expressed his frustration as follows [28, p. 114]: "I had to handle tensors; but how could I when I was not permitted to see them, being only allowed to learn about their changing costumes under changes of coordinates? I had somehow to grab the rascals, and look straight at them."

[^21]The physical meaning of a vector is not just displacement, but linear displacement. For instance, forces at a point combine in the same way that vectors add (this is an experimental observation), so force is treated as a vector. The physical meaning of a tensor is multilinear displacement. ${ }^{33}$. That means a quantity (mathematical or physical) whose description transforms under a change of coordinates in the same way as the components of a tensor can be mathematically described as that type of tensor. Some examples of this in physics, including the physical reasoning behind the effect of a change of coordinates, are in [6, Chap. 31].
Example 7.3. The most basic example of a rank-2 tensor in mechanics is the stress tensor. When a force is applied to a body the stress it imparts at a point may not be in the direction of the force but in some other direction (compressing a piece of clay, say, can push it out orthogonally to the direction of the force), and this effect is linear in the input, so stress at a point is described by a linear transformation, and thus is a rank-2 tensor since $\operatorname{End}(V) \cong V^{\vee} \otimes V$ (Example 5.11). Since stress from an applied force can act in different directions at different points, the stress tensor is not really a single tensor but rather is a varying family of tensors at different points: stress is a tensor field, which is a generalization of a vector field. A tensor field on a manifold $M$ can be defined locally or globally:

- (Locally) A $(k, \ell)$-tensor field on $M$ is a choice of element in each tensor product $T_{p}(M)^{\otimes k} \otimes_{\mathbf{R}} T_{p}(M)^{\vee \otimes \ell}$ of tangent and cotangent spaces at the points $p$ on $M$, varying smoothly with $p$,
- (Globally) A $(k, \ell)$-tensor field on $M$ is an element of $\mathfrak{X}(M)^{\otimes k} \otimes_{C^{\infty}(M)} \mathfrak{X}(M)^{\vee \otimes \ell}$ where $\mathfrak{X}(M)$ is the set of all vector fields on $M$ viewed as a module over the ring $C^{\infty}(M)$ of smooth functions on $M[14$, Sect. $7.2,7.3]$.
Tensors in many parts of physics (classical mechanics, electromagnetism, and relativity) are always part of a tensor field, and in physics the word "tensor" often means "tensor field". A change of variables between local coordinate systems $x=\left\{x^{i}\right\}$ and $y=\left\{y^{i}\right\}$ in a region of $\mathbf{R}^{n}$ involves partial derivatives $\frac{\partial y^{i}}{\partial x^{j}}$ or (in the reverse direction) $\frac{\partial x^{i}}{\partial y^{j}}$ : by the chain rule, $\frac{\partial}{\partial x^{j}}=\sum_{i} \frac{\partial y^{i}}{\partial x^{j}} \frac{\partial}{\partial y^{i}}$ and $\frac{\partial}{\partial y^{j}}=\sum_{i} \frac{\partial x^{i}}{\partial y^{j}} \frac{\partial}{\partial x^{i}}$. Tensor transformation rules when working with tensor fields occur with $\frac{\partial y^{i}}{\partial x^{j}}$ and $\frac{\partial x^{i}}{\partial y^{j}}$, which vary from point to point, in the role of $a_{i j}$ and $a^{i j}$. For example, a tensor of rank 2 with upper indices is a doubly-indexed quantity $T^{i j}(\mathrm{x})$ in each coordinate system x at a point, such that in a second coordinate system y at the same point its components are

$$
\begin{equation*}
\widetilde{T}^{i j}(\mathrm{y})=\sum_{k, \ell=1}^{n} T^{k \ell}(\mathrm{x}) \frac{\partial y^{i}}{\partial x^{k}}(\mathrm{x}) \frac{\partial \mathrm{y}^{\mathrm{j}}}{\partial \mathrm{x}^{\ell}}(\mathrm{x}), \tag{7.12}
\end{equation*}
$$

which should be compared to (7.9).
Not every indexed quantity is a tensor: to be a tensor it must satisfy a tensor transformation law under every change of coordinates, such as (7.12) to be a (2,0)-tensor. An example of an indexed quantity that is not a tensor is the Christoffel symbols $\Gamma_{i j}^{k}$ (components of a Levi-Civita connection). Under a change in coordinates they do not transform by a multilinear change of variables, so they have 3 indices but they are not a rank 3 tensor.

To see a physicist introduce tensors (really, tensor fields) as indexed quantities, watch Leonard Susskind's lectures on general relativity on YouTube from 2009, particularly lecture

[^22]3 (tensors first appear 42 minutes in, although some notation is introduced earlier) and lecture 4. In lecture 5 tensor calculus (covariant differentiation of tensor fields) is introduced.

Physicists and engineers who think of tensors in terms of their components will say that a physical law described with tensors is independent of coordinates because such a law in one coordinate system has a similar description in any other coordinate system. What often goes unmentioned is that these physical laws are multilinear relations among tensor components, which is the reason for independence of coordinates since the components of a tensor transform multilinearly when coordinates change. I have seen some references for physicists or engineers go as far as to assert the converse: a physical law that is independent of coordinates must be expressible in terms of tensors, but that's wrong: tensor fields are not the only concept in geometry that is independent of coordinates. For example, connections and spinor fields are geometric structures on (Riemannian) manifolds that are not tensors.

Tensors play an essential role in quantum mechanics, but for rather different reasons than we've already mentioned in physics. In classical mechanics, the states of a system are modeled by the points on a finite-dimensional manifold, and when we combine two systems the corresponding manifold is the direct product of the manifolds for the original two systems. The states of a quantum system, on the other hand, are represented by the nonzero vectors (really, the 1-dimensional subspaces) in a complex Hilbert space, such as $L^{2}\left(\mathbf{R}^{6}\right)$. (A point in $\mathbf{R}^{6}$ has three position and three momentum coordinates, which is the classical description of a particle.) When we combine two quantum systems, its corresponding Hilbert space is the tensor product of the original Hilbert spaces, essentially because $L^{2}\left(\mathbf{R}^{6} \times \mathbf{R}^{6}\right)=L^{2}\left(\mathbf{R}^{6}\right) \otimes_{\mathbf{C}} L^{2}\left(\mathbf{R}^{6}\right)$, which is the analytic ${ }^{34}$ analogue of $R[X, Y] \cong$ $R[X] \otimes_{R} R[Y]$. Thus quantum states are related to tensors in a single tensor product of Hilbert spaces, not to tensor fields. A video of a physicist introducing tensor products of Hilbert spaces on YouTube is Frederic Schuller's lecture 14 on quantum mechanics, where he writes an elementary tensor as $v \boxtimes w$ rather than $v \otimes w$ to avoid confusion with the use of $\otimes$ in the notation of the vector space $H_{1} \otimes_{\mathbf{C}} H_{2}$.

The difference between a direct product of manifolds $M \times N$ and a tensor product of vector spaces $H_{1} \otimes_{\mathbf{C}} H_{2}$ reflects mathematically some of the non-intuitive features of quantum mechanics. Every point in $M \times N$ is a pair $(x, y)$ where $x \in M$ and $y \in N$, so we get a direct link from a point in $M \times N$ to something in $M$ and something in $N$. On the other hand, most tensors in $H_{1} \otimes_{\mathbf{C}} H_{2}$ are not elementary, and a non-elementary tensor in $H_{1} \otimes_{\mathbf{C}} H_{2}$ has no simple-minded description in terms of a pair of elements of $H_{1}$ and $H_{2}$. Quantum states in $H_{1} \otimes_{\mathbf{C}} H_{2}$ that correspond to non-elementary tensors are called entangled states, and they reflect the difficulty of trying to describe quantum phenomena for a combined system (e.g., the two-slit experiment) in terms of quantum states of the two original systems individually. I've been told that physics students who get used to computing with tensors in relativity by learning to work with the "transform by a definite rule" description of tensors find the role of tensors in quantum mechanics to be difficult to learn, because the conceptual role of tensors there is so different. And probably it doesn't help students that physicists use "tensor" to mean both tensor fields and tensors.

Whether you want to think of tensors as objects in a space having a universal mapping property, indexed quantities that satisfy a transformation rule, or a physical interpretation,

[^23]the advice of user mathwonk on the website PhysicsForums ${ }^{35}$ is worth remembering: It does not matter what a "tensor" is, what matters is knowing what you are doing.

We'll end this discussion of tensors in physics with a story. I was the math consultant for the 4 th edition of the American Heritage Dictionary of the English Language (2000). The editors sent me all the words in the 3rd edition with mathematical definitions, and I had to find and correct the errors. Early on I came across a word I had never heard of before: dyad. It was defined in the 3 rd edition as "an operator represented as a pair of vectors juxtaposed without multiplication." That's a ridiculous definition, as it conveys no meaning at all. I obviously had to fix this definition, but first I had to know what the word meant! In a physics book ${ }^{36}$ a dyad is defined as "a pair of vectors, written in a definite order ab." This is just as useless, but the physics book also does something with dyads, which gives a clue about what they really are. The product of a dyad $\mathbf{a b}$ with a vector $\mathbf{c}$ is $\mathbf{a}(\mathbf{b} \cdot \mathbf{c})$, where $\mathbf{b} \cdot \mathbf{c}$ is the usual dot product ( $\mathbf{a}, \mathbf{b}$, and $\mathbf{c}$ are all vectors in $\mathbf{R}^{n}$ ). This reveals what a dyad is. Do you see it? Dotting with $\mathbf{b}$ is an element of the dual space $\left(\mathbf{R}^{n}\right)^{\vee}$, so the effect of $\mathbf{a b}$ on $\mathbf{c}$ is reminiscient of the way $V \otimes V^{\vee}$ acts on $V$ by $(v \otimes \varphi)(w)=\varphi(w) v$. A dyad is the same thing as an elementary tensor $v \otimes \varphi$ in $\mathbf{R}^{n} \otimes\left(\mathbf{R}^{n}\right)^{\vee}$. In the 4 th edition of the dictionary, I included two definitions for a dyad. For the general reader, a dyad is "a function that draws a correspondence ${ }^{37}$ from any vector $\mathbf{u}$ to the vector $(\mathbf{v} \cdot \mathbf{u}) \mathbf{w}$ and is denoted $\mathbf{v w}$, where $\mathbf{v}$ and $\mathbf{w}$ are a fixed pair of vectors and $\mathbf{v} \cdot \mathbf{u}$ is the scalar product of $\mathbf{v}$ and $\mathbf{u}$. For example, if $\mathbf{v}=(2,3,1)$, $\mathbf{w}=(0,-1,4)$, and $\mathbf{u}=(a, b, c)$, then the dyad $\mathbf{v w}$ draws a correspondence from $\mathbf{u}$ to $(2 a+3 b+c) \mathbf{w}$." The more concise second definition was: a dyad is "a tensor formed from a vector in a vector space and a linear functional on that vector space." Unfortunately, the definition of "tensor" in the dictionary is "A set of quantities that obey certain transformation laws relating the bases in one generalized coordinate system to those of another and involving partial derivative sums. Vectors are simple tensors." That is really the definition of a tensor field, and that sense of the word tensor is incompatible with my concise definition of a dyad in terms of tensors.

More general than a dyad is a dyadic, which is a sum of dyads: $\mathbf{a b}+\mathbf{c d}+\ldots$. So a dyadic is a general tensor in $\mathbf{R}^{n} \otimes_{\mathbf{R}}\left(\mathbf{R}^{n}\right)^{\vee} \cong \operatorname{Hom}_{\mathbf{R}}\left(\mathbf{R}^{n}, \mathbf{R}^{n}\right)$. In other words, a dyadic is an $n \times n$ real matrix. The terminology of dyads and dyadics goes back to Gibbs [7, Chap. 3], who championed the development of linear and multilinear algebra, including his indeterminate product (that is, the tensor product), under the name "multiple algebra."

[^0]:    ${ }^{1}$ Recall a spanning set for an $R$-module is a subset whose finite $R$-linear combinations fill up the module. They always exist, since the entire module is a spanning set.

[^1]:    ${ }^{2}$ Compare with the polynomial ring $R[X, Y]$, whose elements are not only products $f(X) g(Y)$, but sums of such products $\sum_{i, j} a_{i j} X^{i} Y^{j}$. It turns out that $R[X, Y] \cong R[X] \otimes_{R} R[Y]$ as $R$-modules (Example 4.12).
    ${ }^{3}$ Gibbs chose that label since this product was, in his words, "the most general form of product of two vectors," as it is subject to no laws except bilinearity, which must be satisfied by any operation deserving to be called a product. In 1844, Grassmann created a special tensor called an "open product" [20, Chap. 3].

[^2]:    ${ }^{4}$ Writing $\mathbf{i}, \mathbf{j}$, and $\mathbf{k}$ for the standard basis of $\mathbf{R}^{3}$, Gibbs called a sum $a \mathbf{i} \otimes \mathbf{i}+b \mathbf{j} \otimes \mathbf{j}+c \mathbf{k} \otimes \mathbf{k}$ with positive $a, b$, and $c$ a right tensor [7, p. 57], but I don't know if this had an influence on Voigt's terminology.
    ${ }^{5}$ I thank Jim Casey for bringing [17] to my attention.

[^3]:    ${ }^{6}$ The universal mapping property is not about modules $T$ per se, but about pairs $(T, b)$.

[^4]:    ${ }^{7}$ What happens if $R$ is a noncommutative ring? If $M$ and $N$ are left $R$-modules and $B$ is bilinear on $M \times N$ then for all $m \in M, n \in N$, and $r$ and $s$ in $R, r s B(m, n)=r B(m, s n)=B(r m, s n)=s B(r m, n)=$ $s r B(m, n)$. Usually $r s \neq s r$, so asking that $r s B(m, n)=s r B(m, n)$ for all $m$ and $n$ puts us in a delicate situation! The correct tensor product $M \otimes_{R} N$ for noncommutative $R$ uses a right $R$-module $M$, a left $R$ module $N$, and a "middle-linear" map $B$ where $B(m r, n)=B(m, r n)$. In fact $M \otimes_{R} N$ is not an $R$-module but just an abelian group! While we won't deal with tensor products over a noncommutative ring, they are important. They appear in the construction of induced representations of groups.
    ${ }^{8}$ For $R \neq 0$, an explicit example of a nonelementary tensor in $R^{2} \otimes_{R} R^{2}$ will be provided in Example 4.11. We essentially already met one in Example 2.1 when we saw $e_{1} e_{1}^{\top}+e_{2} e_{2}^{\top} \neq \mathbf{v w}^{\top}$ for all $\mathbf{v}$ and $\mathbf{w}$ in $\mathbf{R}^{n}$.

[^5]:    ${ }^{9}$ In Brad Osgood's notes on the Fourier transform [19, pp. 343-344], he writes about functions of the form $f_{1}\left(x_{1}\right) f_{2}\left(x_{2}\right) \cdots f_{n}\left(x_{n}\right)$ "If you really want to impress your friends and confound your enemies, you can invoke tensor products in this context. [...] People run in terror from the $\otimes$ symbol. Cool."

[^6]:    ${ }^{10}$ See http://mathbabe.org/2011/07/20/what-tensor-products-taught-me-about-living-my-life/.

[^7]:    ${ }^{11}$ Each part of an elementary tensor in $M \otimes_{R} N$ belongs to $M$ or to $N$.

[^8]:    ${ }^{12}$ If $F^{\prime}=F$, then (4.1) shows a necessary condition for $\sum_{i, j=1}^{n} c_{i j} e_{i} \otimes e_{j}$ to be elementary is $c_{i i} c_{j j}=c_{i j} c_{j i}$ for all $i$ and $j$. When $R=K$ is a field this condition is also sufficient, so in $K^{n} \otimes_{K} K^{n}$ the elementary tensors are characterized among all tensors by polynomial equations of degree 2 . For more on this, see [9].

[^9]:    ${ }^{13}$ Unless every tensor in $M \otimes_{R} N$ is elementary, which is usually not the case.
    ${ }^{14}$ See Example 5.19 for an example of a linear map $M \otimes_{R} N \rightarrow P$ that is not injective on $M \otimes_{R} N$ and is injective on the elementary tensors in $M \otimes_{R} N$.

[^10]:    ${ }^{15}$ Theorem 4.21 is just a special case of Theorem 4.23 , but we worked it out separately first since the technicalities are simpler.

[^11]:    ${ }^{16}$ A general elementary tensor in $\left(M \otimes_{R} N\right) \otimes_{R} P$ is not $(m \otimes n) \otimes p$, but $t \otimes p$ where $t \in M \otimes_{R} N$ and $t$ might not be elementary itself. Similarly, elementary tensors in $M \otimes_{R}\left(N \otimes_{R} P\right)$ are more general than $m \otimes(n \otimes p)$.

[^12]:    ${ }^{17}$ When $R$ is a field, so $M$ and the $N_{i}$ 's are vector spaces, (5.2) is an isomorphism.

[^13]:    ${ }^{18}$ Using the first isomorphism in Corollary 5.8 and double duality, $M \otimes_{R} N \cong \operatorname{Bil}_{R}(M, N ; R)^{\vee}$ for finite free $M$ and $N$, where $m \otimes n$ in $M \otimes_{R} N$ corresponds to the function $B \mapsto B(m, n)$ in $\operatorname{Bil}_{R}(M, N ; R)^{\vee}$. This is how tensor products of finite-dimensional vector spaces are defined in [10, p. 40], namely $V \otimes_{K} W$ is defined to be the dual space to $\operatorname{Bil}_{K}(V, W ; K)$.

[^14]:    ${ }^{19}$ Different $v$ 's might have all the same coefficients for $L(v)$ if $L$ is not injective.
    ${ }^{20}$ Here is a more direct way to show each elementary tensor $c_{i} \otimes e_{i}$ is nonzero. Each $e_{i}$ is in $L(V)$ and is not 0 , so there is a $v$ where $L(v)=e_{i}$, and for that $v$ we have $c_{i}(v)=1$ (and other $c_{j}(v)$ are 0 ). Thus $c_{i} \neq 0$ in $V^{\vee}$, so $c_{i} \otimes e_{i}$ is nonzero by Theorem 4.25 (or 4.9).

[^15]:    ${ }^{21}$ See https://mathoverflow.net/questions/102559.

[^16]:    ${ }^{22}$ We saw $S \otimes_{R} R[X]$ and $S[X]$ are isomorphic as $R$-modules in Example 4.16 when $S \supset R$, and it holds now for all $R \xrightarrow{f} S$.

[^17]:    ${ }^{23}$ When $R$ is not a domain, this concept of rank for $R$-modules is not quite the right one.

[^18]:    ${ }^{24}$ These scaling formulas are not really definitions of scalar multiplication by $K$ on $V \otimes_{R} W$, since tensors are not unique sums of elementary tensors. That such scaling formulas are well-defined operatios on $V \otimes_{K} W$ requires creating the scaling functions as in the proof of part 1 of Theorem 6.15.

[^19]:    ${ }^{25}$ Physicists are interested only in real or complex vector spaces.
    ${ }^{26}$ This meaning of the term "rank of a tensor" as the number of indices is unrelated to the meaning of "rank of a tensor" near the end of Section 5 in terms of a sum of elementary tensors.
    ${ }^{27}$ We really should speak of an ordered basis of $V$, since $e_{1} \otimes e_{2} \neq e_{2} \otimes e_{1}$.
    ${ }^{28}$ Strictly speaking we aren't using every possible basis of $V^{\otimes k}$ but only bases of $V^{\otimes k}$ built as $k$-fold elementary tensors from a basis of $V$.

[^21]:    ${ }^{30}$ See https://einsteinpapers.press.princeton.edu/vol6-trans/169.
    ${ }^{31}$ I thank Don Marolf for bringing this point to my attention.
    ${ }^{32}$ The earliest reference I know that describes tensors using multilinearity instead of components with a transformation rule is [21, pp. 179], from 1923, which confuses $V$ with its dual space.

[^22]:    ${ }^{33}$ Tensors are "multilinear functions of several directions" in [24, p. 9].

[^23]:    ${ }^{34}$ This tensor product should be completed, having infinite sums of products $f(\mathbf{x}) g(\mathbf{y})$. There are more subtleties. See http://www-users.math.umn.edu/~garrett/m/v/nonexistence_tensors.pdf and https:// math.stackexchange.com/questions/2951879.

    ${ }^{37}$ Yes, this terminology sucks. Blame the unknown editor at the dictionary for that one.
