1. Introduction

A complex number is a sum $a + bi$ with $a, b \in \mathbb{R}$ and $i^2 = -1$. Addition and multiplication are given by the rules

$$(a + bi) + (c + di) = (a + c) + (b + d)i, \quad (a + bi)(c + di) = (ac - bd) + (ad + bc)i.$$  

This definition doesn’t explain what $i$ “is”. In 1833, Hamilton [3, p. 81] proposed bypassing the mystery about the meaning of $i$ by declaring $a + bi$ to be an ordered pair $(a, b)$. That is, he defined $\mathbb{C}$ to be $\mathbb{R}^2$ with addition and multiplication rules inspired by (1.1):

$$(a, b) + (c, d) = (a + c, b + d), \quad (a, b)(c, d) = (ac - bd, ad + bc).$$

The additive identity is $(0, 0)$, the multiplicative identity is $(1, 0)$, and from addition and scalar multiplication of real vectors we have $(a, b) = (a, 0) + (0, b) = a(1, 0) + b(0, 1)$, which looks like $a + bi$ if we define $i$ to be $(0, 1)$. Real numbers occur as the pairs $(a, 0)$.

Hamilton asked himself if it was possible to multiply triples $(a, b, c)$ in a nice way that extends multiplication of complex numbers $(a, b)$ when they are thought of as triples $(a, b, 0)$. In 1843 he discovered a way to multiply in four dimensions, not three, at the cost of abandoning commutativity of multiplication. His construction is called the quaternions.

After meeting the quaternions in Section 2, we will see in Section 3 how they can be generalized to a construction called a quaternion algebra. Sections 4 and 5 explore quaternion algebras over fields not of characteristic 2.

2. Hamilton’s Quaternions

**Definition 2.1.** The *quaternions* are

$$\mathbb{H} = \{a + bi + cj + dk : a, b, c, d \in \mathbb{R}\},$$

where the following multiplication conditions are imposed:

- $i^2 = j^2 = k^2 = -1,$
- $ij = k, \ ji = -k, \ jk = i, \ kj = -i, \ ki = j, \ ik = -j$,
- every $a \in \mathbb{R}$ commutes with $i, j,$ and $k$.

To remember the rules for multiplying $i, j,$ and $k$ by each other, put them in alphabetical order around a circle as below. Products following this order get a plus sign, and products going against the order get a minus sign, e.g., $jk = i$ and $ik = -j$. 

\[i \quad j \quad k\]

1
The rules for multiplying $i$, $j$, and $k$ by themselves and by each other are enough, with the distributive law, to multiply any two quaternions.

**Example 2.2.** $(i + j)(i - j) = i^2 - ij + ji - j^2 = -1 - k - k - (-1) = -2k$, while $i^2 - j^2 = 1 - (-1) = 0$.

**Example 2.3.** A quaternion with $a = 0$ is called a pure quaternion, and the square of a pure quaternion is a negative sum of three squares:

$$
(2.1) \quad (bi + cj + dk)^2 = -b^2 - c^2 - d^2.
$$

While multiplication in $H$ is typically noncommutative, multiplication in $H$ by real numbers is commutative: $aq = qa$ when $a \in \mathbb{R}$ and $q \in H$. This commuting property singles out $\mathbb{R}$ inside $H$: the only quaternions that commute with all quaternions are real numbers (Exercise 2.2). In the terminology of ring theory, the set of elements of a ring that commute with every element of the ring is called the center of the ring, so the center of $H$ is $\mathbb{R}$. The ring $M_2(\mathbb{R})$ also has center $\mathbb{R}$: the matrices in $M_2(\mathbb{R})$ that commute with all matrices in $M_2(\mathbb{R})$ are the scalar diagonal matrices $(\begin{smallmatrix} a & 0 \\ 0 & a \end{smallmatrix}) = aI_2$, which is a natural copy of $\mathbb{R}$ in $M_2(\mathbb{R})$.

For a quaternion $q = a + bi + cj + dk$, its conjugate $\overline{q}$ is defined to be

$$
\overline{q} = a - bi - cj - dk.
$$

This is analogous to complex conjugation on $C$, where $\overline{a + bi} = a - bi$. Complex conjugation interacts well with addition and multiplication in $C$:

\[
\overline{z + w} = \overline{z} + \overline{w}, \quad \overline{zw} = z\overline{w}.
\]

For $z = a + bi$ in $C$, $z\overline{z} = a^2 + b^2$. The absolute value $|a + bi|$ is defined to be $\sqrt{a^2 + b^2}$, so $|z|^2 = z\overline{z}$. If $z \neq 0$ in $C$ then $|z| > 0$ and $1/z = \overline{z}/|z|^2$.

Conjugation on $H$ has properties similar to conjugation on $C$: in $H$,

\[
(2.2) \quad \overline{q_1 + q_2} = \overline{q_1} + \overline{q_2}, \quad \overline{q_1q_2} = \overline{q_1}\overline{q_2}, \quad \overline{q} = q.
\]

Note that conjugation switches the order of multiplication. The norm of $q$ is

$$
N(q) = \overline{q}q = a^2 + b^2 + c^2 + d^2.
$$

It turns out that $\overline{q}q = q\overline{q}$, so $q$ commutes with its conjugate. This implies that the norm is multiplicative:

\[
(2.3) \quad N(q_1q_2) = q_1q_2\overline{q_1\overline{q_2}} = q_1q_2\overline{q_2q_1} = q_1N(q_2)\overline{q_1} = q_1\overline{q_1}N(q_2) = N(q_2)N(q_1).
\]

If $q \neq 0$ then $N(q) > 0$, so $\overline{q}/N(q)$ is an inverse for $q$ on both the left and right:

$$
q\frac{\overline{q}}{N(q)} = \frac{q}{N(q)}q = \frac{N(q)}{N(q)} = 1.
$$

**Example 2.4.** The quaternion $i + j$ has conjugate $-i - j$ and norm 2, so the inverse of $i + j$ is $\frac{1}{2}(-i - j)$.

A ring in which every nonzero element has a two-sided multiplicative inverse is called a division ring, so $H$ is a division ring. We set $H^* = H - \{0\}$, just like with fields. A commutative division ring is a field, and the center of a division ring is a field (Exercise 2.3). The quaternions were the first example of a noncommutative division ring, and the following theorem provides a conceptual role for them in algebra among all division rings.

**Theorem 2.5** (Frobenius, 1878). Any division ring with center $R$ that is finite-dimensional as a vector space over $R$ is isomorphic to $R$ or $H$. 

Proof. See [4, pp. 219–220]. □

Although \( \mathbb{C} \) is a division ring and is finite-dimensional over \( \mathbb{R} \), it is not part of the list in the conclusion of this theorem since the center of \( \mathbb{C} \) is \( \mathbb{C} \), not \( \mathbb{R} \).

Multiplication in \( \mathbb{H} \) is not commutative, but it is associative. To prove associativity of multiplication might seem like a nightmare. One way to avoid checking associativity of multiplication directly is by embedding \( \mathbb{H} \) into a known ring so that quaternionic ring operations are special instances of addition and multiplication in the known ring. Then associativity in \( \mathbb{H} \) automatically follows from associativity in the known ring. This can be done by embedding \( \mathbb{H} \) into \( \text{M}_2(\mathbb{C}) \) in a manner that is analogous to representing complex numbers by \( 2 \times 2 \) real matrices. Let’s review the case of complex numbers first.

To each complex number \( a + bi \) associate the real matrix \( \left( \begin{array}{cc} a & -b \\ b & a \end{array} \right) \). These matrices add and multiply in the same way that complex numbers add and multiply in (1.1):

\[
\left( \begin{array}{cc} a & -b \\ b & a \end{array} \right) + \left( \begin{array}{cc} c & -d \\ d & c \end{array} \right) = \left( \begin{array}{cc} a+c & -(b+d) \\ b+d & a+c \end{array} \right),
\]

\[
\left( \begin{array}{cc} a & -b \\ b & a \end{array} \right) \left( \begin{array}{cc} c & -d \\ d & c \end{array} \right) = \left( \begin{array}{cc} ac-bd & -(ad+bc) \\ ad+bc & ac-bd \end{array} \right).
\]

Since \( \left( \begin{array}{cc} a & -b \\ b & a \end{array} \right) = a \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right) + b \left( \begin{array}{cc} 0 & -1 \\ -1 & 0 \end{array} \right) \), the number \( i \) corresponds to \( \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) \).

To express \( \mathbb{H} \) using \( 2 \times 2 \) complex matrices, we switch from thinking of \( \mathbb{H} \) as 4-dimensional with real scalars and basis \( 1, i, j, k \), to being 2-dimensional with complex scalars\(^1\) and basis \( 1, j \) by writing

\[ q = a + bi + cj + dk = (a + bi) + (c + di)j = z + wj, \]

where \( z = a + bi \) and \( w = c + di \). The quaternions can be embedded into \( \text{M}_2(\mathbb{C}) \) by associating to each quaternion \( q = z + wj \) the complex matrix

\[
m_q = \left( \begin{array}{cc} z & -w \\ w & \bar{z} \end{array} \right).
\]

For instance, \( m_1 = \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) \), \( m_i = \left( \begin{array}{cc} 0 & -1 \\ 1 & 0 \end{array} \right) \), \( m_j = \left( \begin{array}{cc} 0 & -1 \\ -1 & 0 \end{array} \right) \), and \( m_k = \left( \begin{array}{cc} 0 & -i \\ -i & 0 \end{array} \right) \). Check \( m_{q+q'} = m_q + m_{q'} \) and \( m_{qq'} = m_q m_{q'} \), so \( q \mapsto m_q \) respects addition and multiplication. This is injective as well, so the mapping \( q \mapsto m_q \) lets us think of \( \mathbb{H} \) as a subring of \( \text{M}_2(\mathbb{C}) \). Then associativity of matrix multiplication implies associativity of multiplication in \( \mathbb{H} \). The multiplicative rules involving any two of \( i, j, \) and \( k \) can be derived from \( i^2 = j^2 = k^2 = -1 \) and \( ij = k = -ji \) using associativity, e.g.,

\[
k^2 = (ij)(ij) = (ij)(-ji) = i(-j^2)i = i(-(-1))i = i^2 = -1,
\]

\[
jk = j(ij) = (ji)j = -(ij)j = -i(jj) = -i(-1) = i,
\]

\[
jk = i(ij) = (ii)j = -j.
\]

Conjugation and the norm of a quaternion \( q \) can also be described in terms of matrix operations on \( m_q \): \( m_q^* = \overline{m_q} \) and \( N(q) = \text{det} m_q \).

Although \( \mathbb{H} \) is four-dimensional, it can describe rotations in \( \mathbb{R}^3 \) by using the “rotation as conjugation” point of view on the three-dimensional subspace of pure quaternions in \( \mathbb{H} \), which is described in Exercise 2.7 (a), (c). See also [2, Chap. 7] or [6, Sect. 5]. In computer code, the composition of rotations when described in terms of multiplication of quaternions has some advantages over other approaches to rotations (no “gimbal lock” and less data to

\(^1\)Since \( zq \) and \( qz \) are usually not the same for \( z \in \mathbb{C} \) and \( q \in \mathbb{H} \), we can think about \( \mathbb{H} \) as a vector space over \( \mathbb{C} \) in two ways: as a left \( \mathbb{C} \)-vector space with \( z \cdot q = zq \) and as a right \( \mathbb{C} \)-vector space with \( z \cdot q = qz \).
store: 4 coordinates of a quaternion vs. 9 components of a matrix). This makes quaternions a practical tool in computer graphics (search on the internet for “slerp”).

Exercises.

1. Verify properties of quaternionic conjugation: \( \bar{q_1 + q_2} = \bar{q}_1 + \bar{q}_2, \bar{q_1q_2} = \bar{q}_2\bar{q}_1, \bar{q} = q, \quad \Omega q = c\Omega \) for \( c \in \mathbb{R} \), and \( \bar{q} = q \iff q \in \mathbb{R} \).

2. Show the center of \( \mathbb{H} \) is \( \mathbb{R} \): \( \{ q \in \mathbb{H} : qq' = q'q \text{ for all } q' \in \mathbb{H} \} = \mathbb{R} \).

3. Show the center of a division ring is a field. (The main point is to show the inverse of a nonzero element in the center is also in the center.)

4. Show the maps \( \mathbb{C} \to M_2(\mathbb{R}) \) given by \( a + bi \mapsto \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \) and \( \mathbb{H} \to M_2(\mathbb{C}) \) given by \( z + wj \mapsto \left( \frac{z}{w}, -\frac{w}{z} \right) \) are injective ring homomorphisms.

5. Verify that the images of \( \mathbb{C} \) in \( M_2(\mathbb{R}) \) and \( \mathbb{H} \) in \( M_2(\mathbb{C}) \) from the previous exercise can be described as follows: \( \mathbb{C} = \{ A \in M_2(\mathbb{R}) : \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} A = A \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \} \) and \( \mathbb{H} = \{ A \in M_2(\mathbb{C}) : \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} A = \bar{A} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \} \), where \( \bar{A} \) is the matrix with complex conjugate entries to \( A \).

6. For \( q \in \mathbb{H}^x \), let \( R_q : \mathbb{H} \to \mathbb{H} \) by \( R_q(r) = qrq^{-1} \).
   a) Show \( R_q \) is a ring automorphism of \( \mathbb{H} \).
   b) Show \( R_{q_1} \circ R_{q_2} = R_{q_1q_2} \). Does \( R_{q_1+q_2} = R_{q_1} + R_{q_2} \)?
   c) For \( q, q' \in \mathbb{H}^x \), show \( R_q(r) = R_{q'}(r) \) for all \( r \in \mathbb{H} \) if and only if \( q' = cq \) for some \( c \in \mathbb{R}^x \).

7. Let \( \mathbb{H}^0 = Ri + Rj + Rk \). These are the pure quaternions. Define \( \text{Tr} : \mathbb{H} \to \mathbb{R} \) by \( \text{Tr}(q) = q + \bar{q} = 2a \), where \( a \) is the real component of \( q \). The number \( \text{Tr}(q) \) is called the trace of \( q \). Then \( \mathbb{H}^0 = \{ q \in \mathbb{H} : \text{Tr}(q) = 0 \} \).
   a) Show \( \text{Tr}(qq') = \text{Tr}(q'q) \) for all \( q \) and \( q' \) in \( \mathbb{H} \). Use this to show \( R_q(\mathbb{H}^0) = \mathbb{H}^0 \) for all \( q \in \mathbb{H}^x \), where \( R_q \) is defined in the previous exercise.
   b) If \( R_q(r) = R_{q'}(r) \) for all \( r \in \mathbb{H}^0 \), is \( q' = cq \) for some \( c \in \mathbb{R}^x \)?
   c) Show \( \mathbb{H}^0 = \{ q \in \mathbb{H} : q^2 = 0 \} \), and use this to prove in another way that \( R_q(\mathbb{H}^0) = \mathbb{H}^0 \) for all \( q \in \mathbb{H}^x \).
   d) For \( q \in \mathbb{H} \), show \( q^2 = -1 \) if and only if \( q = bi + cj + dk \) with \( b^2 + c^2 + d^2 = 1 \). That is, the solutions to \( q^2 + 1 = 0 \) in \( \mathbb{H} \) form a sphere of pure quaternions.

8. Identify \( \mathbb{H}^0 \) with \( \mathbb{R}^3 \) by \( (b, c, d) \leftrightarrow (b, c, d) \). If \( q = bi + cj + dk \), write \( q \) for \( (b, c, d) \) as a vector in \( \mathbb{R}^3 \).
   a) Show multiplication of pure quaternions can be described in terms of the dot product and cross product on \( \mathbb{R}^3 \): \( q_1, q_2 \in \mathbb{H}^0 \implies q_1q_2 = -(q_1 \cdot q_2) + (q_1 \times q_2) \), where the cross product \( q_1 \times q_2 \) is computed in \( \mathbb{R}^3 \) and then viewed as a pure quaternion. In particular, \( q_1 \) and \( q_2 \) are perpendicular in \( \mathbb{R}^3 \) if and only if \( q_1 \) and \( q_2 \) anti-commute (that is, \( q_1q_2 = -q_2q_1 \)).
   b) What are the constraints on the coordinates of \( x_1i + x_2j + x_3k \) in order for it to anti-commute with \( i + j \)?
   c) For \( q_1, q_2, q_3 \in \mathbb{H}^0 \), show \( q_1 \times (q_2 \times q_3) = \frac{1}{2}(q_1q_2q_3 - q_2q_3q_1) \).

3. Quaternion Algebras: Introduction

Let \( F \) be a field. Hamilton’s quaternions \( \mathbb{H} \) can be generalized to allow coefficients in \( F \): \( \mathbb{H}(F) = \{ a + bi + cj + dk : a, b, c, d, \in F \} \)
where \(i, j, \) and \(k\) have the same multiplicative rules as in \(H = H(R)\). Conjugation and the norm on \(H(F)\) are defined in the same way as in \(H\), and their properties in (2.2) and (2.3) continue to be valid. If \(F\) does not have characteristic 2, so \(1 \neq -1\) in \(F\), then the center of \(H(F)\) is \(F\). If \(F\) has characteristic 2 then \(H(F)\) is commutative. From now on, \(F\) is assumed to have characteristic not 2.

**Example 3.1.** The ring \(H(Q)\) is a division ring since it is a subring of the division ring \(H(R)\) and the inverse of a nonzero element \(q\) of \(H(Q)\) in \(H(R)\) is \(\bar{q}/N(q)\), which is in \(H(Q)\).

**Example 3.2.** The ring \(H(F_7)\) is not a division ring: \(2^2 + 3^2 + 1^2 = 0\) in \(F_7\), so \((2i + 3j + k)^2 = -2^2 - 3^2 - 1^2 = 0\) using (2.1) in \(H(F_7)\). A quaternion that squares to 0 can’t have a multiplicative inverse, so \(2i + 3j + k\) is a nonzero element of \(H(F_7)\) without a multiplicative inverse in \(H(F_7)\).

A broader generalization of \(H\) than \(H(F)\) was introduced by Dickson in 1906 [1].

**Definition 3.3.** A quaternion algebra over \(F\) is a ring that is a 4-dimensional vector space over \(F\) with a basis \(1, u, v, w\) with the following multiplicative relations: \(u^2 \in F^\times, v^2 \in F^\times, w = uv = -vu\), and every \(c \in F\) commutes with \(u\) and \(v\). When \(a = u^2\) and \(b = v^2\), this ring is denoted \((a, b)_F\).

More explicitly, for \(a\) and \(b\) in \(F^\times\) the ring \((a, b)_F\) looks as follows. As a vector space over \(F\) it can be written as \((a, b)_F = F + Fu + Fv + Fw\), and the multiplicative relations among \(u, v, w,\) and elements of \(F\) are

- \(u^2 = a\) and \(v^2 = b\),
- \(w := uv = -vu\),
- every \(c \in F\) commutes with \(u\) and \(v\).

**Example 3.4.** In this notation \(H(F) = (-1, -1)_F\), so this is a quaternion algebra where \(a = b = -1\).

In Table 1 are products among \(u, v,\) and \(w\), where each entry is the product of the row label times the column label (in that order: multiplication is noncommutative). For example, \(vw = v(uw) = (vu)v = -v^2w = -ab = -bw\). Note \(u, v,\) and \(w\) each square to a nonzero element of \(F\) and they anti-commute: \(uv = -vu, uw = -wu,\) and \(vw = -wv\).

<table>
<thead>
<tr>
<th></th>
<th align="right">(u)</th>
<th align="right">(v)</th>
<th align="right">(w)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(u)</td>
<td align="right">(a)</td>
<td align="right">(w)</td>
<td align="right">(av)</td>
</tr>
<tr>
<td>(v)</td>
<td align="right">(-w)</td>
<td align="right">(b)</td>
<td align="right">(-bu)</td>
</tr>
<tr>
<td>(w)</td>
<td align="right">(-av)</td>
<td align="right">(bu)</td>
<td align="right">(-ab)</td>
</tr>
</tbody>
</table>

**Table 1.** Products of \(u, v,\) and \(w\) in \((a, b)_F\).

We can make a circular diagram for products of \(u, v,\) and \(w\) that is similar to the one for \(i, j,\) and \(k\). In the picture below we write \(u, v,\) and \(w\) in alphabetical order, with 1 on the arc from \(u\) to \(v\), \(-b\) on the arc from \(v\) to \(w\), and \(-a\) on the arc from \(w\) to \(u\). The product of any two is the third one times the number on the arc between the two factors, with an additional sign if the multiplication is going against the arrows, e.g., \(vw = -(b)u = -bu\) and \(uw = -(-a)v = av\).
Example 3.5. We have \((2,3)_Q = Q + Qu + Qv + Qw\) where \(u^2 = 2\), \(v^2 = 3\), and \(w = uv = -vu\) with \(w^2 = -6\).

The multiplicative rules on \(u\), \(v\), and \(w\) are consistent with the axioms of a ring because we can realize the operations in \((a,b)_F\) as addition and multiplication of certain \(2 \times 2\) matrices (Exercise 3.8). Since \(F\) doesn’t have characteristic 2, \((a,b)_F\) is noncommutative because \(u\) and \(v\) don’t commute. The center of \((a,b)_F\) is \(F\) (Exercise 3.2).

Example 3.6. For \(q = x_0 + x_1 u + x_2 v + x_3 w\) in \((2,3)_Q\),
\[
N(q) = x_0^2 - 2x_1^2 - 3x_2^2 + 6x_3^2.
\]

Example 3.7. Generalizing Example 2.3, an element of \((a,b)_F\) with \(x_0 = 0\) is called a pure quaternion. Its square is a scalar: for \(x,y,z \in F\),
\[
(xu + yv + zw)^2 = ax^2 + by^2 - abz^2 \in F.
\]

This property essentially characterizes the pure quaternions (Exercise 3.6 ii).

Theorem 3.8. An element \(q\) of \((a,b)_F\) has a two-sided multiplicative inverse in \((a,b)_F\) if and only if \(N(q) \neq 0\).

Proof. Suppose \(qq' = 1\) for some \(q'\). Then \(N(q)N(q') = N(1) = 1\) in \(F\), so \(N(q) \in F^\times\).

Conversely, suppose \(N(q) \in F^\times\). Since \(N(q)\) commutes with all elements of \((a,b)_F\), the equation \(N(q) = q\overline{q} = \overline{q}q\) can be rewritten as
\[
q \cdot \frac{1}{N(q)} \overline{q} = \frac{1}{N(q)} \overline{q} \cdot q = 1,
\]
so \(\overline{q}/N(q)\) is a 2-sided inverse of \(q\). \(\square\)

Here are quaternion algebras over \(Q\) besides \(H(Q)\) that are division rings.

Theorem 3.9. Let \(a\) be an integer and \(p\) be an odd prime such that \(a \not\equiv \square \mod p\). Then \((a,p)_Q\) is a division ring.

Proof. By Theorem 3.8, to show \((a,p)_Q\) is a division ring it suffices to show every nonzero element of \((a,p)_Q\) has a nonzero norm. We will prove the contrapositive: an element of \((a,p)_Q\) with norm 0 must be 0.

Let \(q = x_0 + x_1 u + x_2 v + x_3 w\) in \((a,p)_Q\). Using the formula for \(N(q)\) in (3.1),
\[
N(q) = x_0^2 - ax_1^2 - px_2^2 + apx_3^2,
\]
so we can’t show \( N(q) = 0 \Rightarrow q = 0 \) using positivity as we can for \( \mathbf{H} \): \( N(q) \) can be either positive or negative. To show \( N(q) = 0 \Rightarrow q = 0 \), the property \( a \neq \square \mod p \) will be crucial.

If \( N(q) = 0 \) then

\[
(3.3) \quad x_0^2 - ax_1^2 - px_2^2 + apx_3^2 = 0 \implies x_0^2 - ax_1^2 = p(x_2^2 - ax_3^2).
\]

Multiplying through the last equation by a common denominator of \( x_0, x_1, x_2, \) and \( x_3 \), we can assume the \( x_i \)'s are all in \( \mathbf{Z} \). Then if we reduce mod \( p \)

\[
x_0^2 - ax_1^2 \equiv 0 \mod p \implies x_0^2 \equiv ax_1^2 \mod p.
\]

If \( x_1 \not\equiv 0 \mod p \) then we can solve for \( a \mod p \) in the congruence to see that \( a \equiv \square \mod p \), which is false. Therefore \( x_1 \equiv 0 \mod p \), so \( x_0^2 \equiv 0 \mod p \), and thus \( x_0 \equiv 0 \mod p \). Then in \( x_0^2 - ax_1^2 = p(x_2^2 - ax_3^2) \) the left side is divisible by \( p^2 \), so \( x_2^2 - ax_3^2 \equiv 0 \mod p \), and an argument similar to the one above shows \( x_2 \) and \( x_3 \) are divisible by \( p \).

Since every \( x_i \) is divisible by \( p \), write \( x_i = px_i' \) with \( x_i' \in \mathbf{Z} \). Then

\[
x_0^2 - ax_1^2 = p(x_2^2 - ax_3^2) \implies p^2(x_0^2 - ax_1^2) = p^2(x_2^2 - ax_3^2) \implies x_0^2 - ax_1^2 = p(x_2^2 - ax_3^2).
\]

This last equation is the same as the right side of \( (3.3) \), with \( x_i' \) in place of \( x_i \). Then as before, each \( x_i' \) is divisible by \( p \), so each \( x_i \) is divisible by \( p^2 \). Repeating this argument shows each \( x_i \) is divisible by \( p \), and thus \( x_i \) must be 0.

\[ \square \]

**Example 3.10.** The rings \( (2,3)_Q \) and \( (2,5)_Q \) are division rings since \( 2 \mod 3 \) and \( 2 \mod 5 \) are not squares.

**Example 3.11.** For prime \( p \) with \( p \equiv 3 \mod 4 \), \( (-1,p)_Q \) is a division ring since \( -1 \not\equiv \square \mod p \). We will look at \( (-1,p)_Q \) for \( p \not\equiv 3 \mod 4 \) in Example 4.19.

**Remark 3.12.** The converse of Theorem 3.9 is false: \( (a,p)_Q \) can be a division ring when \( a \equiv \square \mod p \). For example, \( 3 \equiv \square \mod 11 \) and (3,11)\( _Q \) is a division ring (Example 4.2).

Quaternions are related to hyperbolic manifolds [7], number theory [8, Chap. 5], [9, §III.9], [10], and quadratic forms [5, Chap. III].

Exercises.

1. Verify the multiplication table for \( u, v, w \) in Table 1.
2. Show the center of \( (a,b)_F \) is \( F \).
3. Show the set of elements of \( (a,b)_F \) that anti-commute with \( u \) is \( Fv + Fw \), and the elements of \( (a,b)_F \) that anti-commute with \( u \) and square to \( b \) are those \( xv + yw \) \((x, y \in F)\) such that \( x^2 - ay^2 = 1 \).
4. (Conjugation and norm)
   a) Check properties of conjugation on \( (a,b)_F \)
      \[
      \overline{c} = c' = c = c' \quad c \in F, \quad \overline{q} = q \quad q \in F.
      \]
   b) For \( q = x_0 + x_1u + x_2v + x_3w, \) show \( q\overline{q} = q\overline{q} = \overline{q} \).
5. For \( a \in \mathbf{Z}, \) show that if \( a \equiv 3 \) or \( 5 \mod 8 \) then \( (a,2)_Q \) is a division ring. This should be considered an analogue of Theorem 3.9 when \( p = 2 \).
6. Let \( (a,b)_F^0 \) be pure quaternions in \( (a,b)_F \).
   a) If \( r \) is pure and \( q \) is invertible in \( (a,b)_F \), show \( q\overline{q}^{-1} \) is pure. (Hint: Set \( Tr(q) = q + \overline{q}, \) show \( Tr \) has properties similar to the trace on \( \mathbf{H}, \) and show \( (a,b)_F^0 = \{ q \in (a,b)_F : Tr(q) = 0 \} \).
   b) For \( q \in (a,b)_F, \) show \( q^2 \in F \iff q \in F \) or \( q \) is pure. Therefore the pure quaternions in \( (a,b)_F \) are precisely the \( q \) satisfying \( q^2 \in F \) with \( q \not\in F \), along with 0.
8 KEITH CONRAD

(\text{Hint: write } q = x_0 + q_0 \text{ where } q_0 \text{ is pure. Use the right side to compute } q^2, \text{ noting } x_0 \text{ and } q_0 \text{ commute. By (3.2), } q_0^2 \in F.)

7. Suppose \( a, b \in \mathbb{R}^\times \) with \( a > 0 \). Show \((a, b)_Q\) becomes a subring of \( M_2(\mathbb{R})\) by

\[
1 \mapsto \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad u \mapsto \begin{pmatrix} \sqrt{a} & 0 \\ 0 & -\sqrt{a} \end{pmatrix}, \quad v \mapsto \begin{pmatrix} 0 & -1 \\ -b & 0 \end{pmatrix}, \quad w \mapsto \begin{pmatrix} 0 & \sqrt{ab} \\ \sqrt{ab} & 0 \end{pmatrix}.
\]

8. We want to generalize the embedding of \( \mathbb{H} \) into \( M_2(\mathbb{C}) \) to an embedding of \((a, b)_F\) into a \( 2 \times 2 \) matrix ring.

For \( a \in F^\times \), the ring \( F[t]/(t^2 - a) \) is a field if \( a \neq \square \) in \( F \), while \( F[t]/(t^2 - a) \cong F \times F \) if \( a = \square \) in \( F \). Verify that the map \((a, b)_F \rightarrow M_2(F[t]/(t^2 - a))\) given by

\[
1 \mapsto \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad u \mapsto \begin{pmatrix} t & 0 \\ 0 & -t \end{pmatrix}, \quad v \mapsto \begin{pmatrix} 0 & -1 \\ -b & 0 \end{pmatrix}, \quad w \mapsto \begin{pmatrix} 0 & bt \\ bt & 0 \end{pmatrix},
\]

and extended to all of \((a, b)_F\) by \( F\)-linearity, is an injective ring homomorphism.

4. ISOMORPHISMS BETWEEN QUATERNION ALGEBRAS

An \textit{isomorphism} between two quaternion algebras \( A \) and \( A' \) over a field \( F \) is a ring isomorphism \( f: A \rightarrow A' \) that fixes the elements of \( F \) (that is, \( f(c) = c \) for all \( c \in F \)). To show two quaternion algebras are isomorphic we will take a low-brow approach by working with well-chosen bases of them.

\textbf{Definition 4.1.} A basis of \((a, b)_F\) having the form \( \{1, e_1, e_2, e_1e_2\} \) where \( e_1^2 \in F^\times \), \( e_2^2 \in F^\times \), and \( e_1e_2 = -e_2e_1 \) is called a \textit{quaternionic basis} of \((a, b)_F\).

For instance, the defining basis \( \{1, u, v, w\} \) of \((a, b)_F\) is a quaternionic basis. In any quaternionic basis \((e_1e_2)^2 = -e_1^2e_2^2\) and the three elements \( e_1, e_2, e_1e_2 \) anti-commute.

There are quaternionic bases of \((a, b)_F\) other than \( \{1, u, v, w\} \), and different choices of a quaternionic basis reveal isomorphisms between different quaternion algebras on account of the multiplicative relations among the basis elements:

\begin{enumerate}
\item \( \{1, u, v, vu\} \) is a quaternionic basis of \((a, b)_F\), so \((a, b)_F \cong (b, a)_F\),
\item \( \{1, u, w, uw\} \) is a quaternionic basis of \((a, b)_F\), so \((a, b)_F \cong (a, -ab)_F\),
\item \( \{1, v, w, vw\} \) is a quaternionic basis of \((a, b)_F\), so \((a, b)_F \cong (b, -ab)_F\),
\item \( \{1, cu, dv, (cu)(dv)\} \) is a quaternionic basis of \((a, b)_F\) for all \( c, d \in F^\times \), so \((a, b)_F \cong (ac^2, bd^2)_F\) for all nonzero \( c \) and \( d \) in \( F\).
\end{enumerate}

\textbf{Example 4.2.} The quaternion algebra \((3, 11)_Q\) is a division ring since \((3, 11)_Q \cong (11, 3)_Q \) and \( 11 \neq \square \) mod 3. Therefore we can use Theorem 3.9 with \( a = 11 \) and \( p = 3 \).

Using the second quaternionic basis with \( b = 1 \), \((a, -a) \cong (a, 1)_F\), and with \( b = -1 \) we get \((a, a)_F \cong (a, -1)_F\). Using the fourth quaternionic basis, up to isomorphism \((a, b)_F\) only depends on \( a \) and \( b \) up to multiplication by nonzero squares in \( F^\times \). For instance, \((a, c^2)_F \cong (a, 1)_F\) and \((c^2, b)_F \cong (1, b)_F \cong (b, 1)_F\). The quaternion algebra \((a, 1)_F\) turns out to be a familiar ring.

\textbf{Theorem 4.3.} For all \( a \in F^\times \), \((a, 1)_F \cong M_2(F)\).

This shows the ring \( M_2(F) \) is a quaternion algebra over \( F \) and that

\begin{equation}
(a, c^2)_F \cong (a, -a)_F \cong M_2(F).
\end{equation}
Proof. Send the basis $1, u, v, w$ of $(a,1)_F$ to $M_2(F)$ as follows:

$$1 \mapsto \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad u \mapsto \begin{pmatrix} 0 & 1 \\ a & 0 \end{pmatrix}, \quad v \mapsto \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad w \mapsto \begin{pmatrix} 0 & -1 \\ a & 0 \end{pmatrix}.$$ 

Since $1 \neq -1$ in $F$, $u$ and $v$ are not sent to the same matrix. Extend this mapping by $F$-linearity to a function $(a,b)_F : M_2(F)$:

$$(4.2) \quad x_0 + x_1u + x_2v + x_3w \mapsto \begin{pmatrix} x_0 + x_2 & x_1 - x_3 \\ a(x_1 + x_3) & x_0 - x_2 \end{pmatrix}.$$ 

The image of $1, u, v, w$ in $M_2(F)$ is a linearly independent set, so by a dimension count this $F$-linear mapping $(a,b)_F : M_2(F)$ is a bijection. It fixes $F$, in the sense that $c \in F$ in $(a,b)_F$ goes to $cI_2$ in $M_2(F)$. It is left to the reader to check (4.2) is multiplicative (Exercise 4.1). \hfill \Box

**Definition 4.4.** We call $M_2(F)$, or any quaternion algebra isomorphic to $M_2(F)$, a trivial or split quaternion algebra over $F$. If $(a,b)_F \not\cong M_2(F)$ we say $(a,b)_F$ is a non-split quaternion algebra.

**Example 4.5.** Let $F = \mathbb{R}$. Then

$$(a,b)_\mathbb{R} \cong \begin{cases} H, & \text{if } a < 0 \text{ and } b < 0, \\ M_2(\mathbb{R}), & \text{if } a > 0 \text{ or } b > 0. \end{cases}$$

**Example 4.6.** Let $F = \mathbb{C}$. All elements of $\mathbb{C}^\times$ are squares in $\mathbb{C}$, so $(a,b)_{\mathbb{C}} \cong M_2(\mathbb{C})$ for all $a$ and $b$ in $\mathbb{C}^\times$: all quaternion algebras over $\mathbb{C}$ are split.

These examples tell us that, up to isomorphism, there are two quaternion algebras over $\mathbb{R}$ and one quaternion algebra over $\mathbb{C}$. Over $\mathbb{Q}$ the situation is completely different: there are infinitely many non-isomorphic quaternion algebras over $\mathbb{Q}$. We’ll see this in Section 5.

**Example 4.7.** If $p$ is prime and $p \equiv 1 \mod 4$ then $H(\mathbb{F}_p) \cong M_2(\mathbb{F}_p)$ since $-1$ is a square in $\mathbb{F}_p$. We’ll see in Corollary 4.24 that every quaternion algebra over $\mathbb{F}_p$ is isomorphic to $M_2(\mathbb{F}_p)$.

**Example 4.8.** The quaternion algebras $(2,3)_{\mathbb{Q}}$ and $(2,5)_{\mathbb{Q}}$ are both division rings (Example 3.10), but the quaternion algebras $(2,3)_{\mathbb{R}}$ and $(2,5)_{\mathbb{R}}$ are not division rings: both are isomorphic to $M_2(\mathbb{R})$.

**Definition 4.9.** For $a$ and $b$ in $\mathbb{Q}^\times$ we say $(a,b)_\mathbb{Q}$ splits over $\mathbb{R}$ if $(a,b)_{\mathbb{R}} \cong M_2(\mathbb{R})$ and we say $(a,b)_\mathbb{Q}$ is non-split over $\mathbb{R}$ if $(a,b)_{\mathbb{R}} \not\cong M_2(\mathbb{R})$ (that is, $(a,b)_{\mathbb{R}} \cong H$).

For example, $(2,3)_{\mathbb{Q}}$ and $(2,5)_{\mathbb{Q}}$ both split over $\mathbb{R}$, while $H(\mathbb{Q}) = \mathbb{Q}$ is non-split over $\mathbb{R}$. More generally, for a field extension $F \subset K$ and $a, b \in F^\times$, we say $(a,b)_F$ splits over $K$ when $(a,b)_K \cong M_2(K)$.

Since $(a,b)_\mathbb{Q}$ splits over $\mathbb{R}$ when $a$ or $b$ is positive, while $(a,b)_\mathbb{Q}$ is non-split over $\mathbb{R}$ when $a$ and $b$ are both negative, the formula for $N(q)$ in (3.1) shows the norm on $(a,b)_\mathbb{Q}$ has positive and negative values when $(a,b)_\mathbb{Q}$ splits over $\mathbb{R}$, while the norm on $(a,b)_\mathbb{Q}$ has only positive values (and 0) when $(a,b)_\mathbb{Q}$ is non-split over $\mathbb{R}$. It is a hard theorem that the norm mapping $N : (a,b)_\mathbb{Q} \to \mathbb{Q}$ is surjective when $(a,b)_\mathbb{Q}$ splits over $\mathbb{R}$ and has image $\mathbb{Q}_{\geq 0}$ if $(a,b)_\mathbb{Q}$ is non-split over $\mathbb{R}$.

**Example 4.10.** Since $(2,3)_{\mathbb{Q}}$ is split over $\mathbb{R}$, the equation $x_0^2 - 2x_1^2 - 3x_2^2 + 6x_3^2 = r$ has a rational solution for every $r \in \mathbb{Q}$. 
There are analogies between quadratic fields $\mathbb{Q}(\sqrt{d})$ and quaternion algebras $(a,b)_Q$. Real quadratic fields (when $x^2 - d$ splits into linear factors over $R$) are analogous to the $(a,b)_Q$ that split over $R$ and imaginary quadratic fields (when $x^2 - d$ does not split into linear factors over $R$) are analogous to the $(a,b)_Q$ that are non-split over $R$. See Table 2.

<table>

<td>Non-split over $R$</td>
</tr>
</tbody>
</table>

Table 2. Analogous Quadratic Fields and Quaternion Algebras over $\mathbb{Q}$.

Here are two examples of the analogies.

1. Sign of norm values: There are norm functions $N: \mathbb{Q}(\sqrt{d}) \to \mathbb{Q}$ and $N: (a,b)_Q \to \mathbb{Q}$, where $N(x + y\sqrt{d}) = x^2 - dy^2$ for quadratic fields. If $d > 0$ the norm on $\mathbb{Q}(\sqrt{d})$ has both positive and negative values, while if $d < 0$ the norm on $\mathbb{Q}(\sqrt{d})$ has only positive values (and 0). If $(a,b)_Q$ splits over $R$ then the norm on $(a,b)_Q$ has both positive and negative values, while if $(a,b)_Q$ is non-split over $R$ then the norm on $(a,b)_Q$ has only positive values (and 0).

2. Integral units: The ring $\mathbb{Z}[\sqrt{d}]$ is analogous to the ring $(a,b)_\mathbb{Z} = \mathbb{Z} + \mathbb{Z}u + \mathbb{Z}v + \mathbb{Z}w$. Units in $\mathbb{Z}[\sqrt{d}]$ are those $x + y\sqrt{d}$ with norm ±1, and units (invertible elements) of $(a,b)_\mathbb{Z}$ are the elements with norm ±1. If $d > 0$ there are infinitely many units in $\mathbb{Z}[\sqrt{d}]$ (theory of Pell’s equation), but if $d < 0$ the unit group of $\mathbb{Z}[\sqrt{d}]$ is finite. If $(a,b)_Q$ splits over $R$ then $(a,b)_\mathbb{Z}$ has infinitely many units, while if $(a,b)_Q$ is non-split over $R$ then $(a,b)_\mathbb{Z}$ has finitely many units.

A more subtle analogy is that when $d > 0$ and $(a,b)_Q$ is split over $R$, the infinitely many units in $\mathbb{Z}[\sqrt{d}]$ and $(a,b)_\mathbb{Z}$ both form finitely-generated groups.

Example 4.11. The quaternion algebra $(2,3)_\mathbb{Q}$ is split over $R$, so infinitely many elements of $(2,3)_\mathbb{Z}$ have norm ±1. Some examples are $1 + u$ (similar to $1 + \sqrt{2}$ in $\mathbb{Z}[\sqrt{2}]$), $2 + v$ (similar to $2 + \sqrt{3}$ in $\mathbb{Z}[\sqrt{3}]$), and $(1 + u)^2(2 + v) = 6 + 4u + 3v + 2u$.

The easiest way to know $(a,b)_F \cong M_2(F)$ is when $b = 0$ in $F^\times$ (see (4.1)). There is a weaker condition on $b$ than being a square that still implies $(a,b)_F \cong M_2(F)$, and to describe this condition we need to know something about numbers of the form $x^2 - ay^2$.

Lemma 4.12. For $a \in F^\times$, the set of nonzero $x^2 - ay^2$ with $x, y \in F$ is a subgroup of $F^\times$.

Proof. The number 1 has this form ($x = 1, y = 0$). Number of this form are closed under multiplication since

$$(x_1^2 - ay_1^2)(x_2^2 - ay_2^2) = (x_1x_2 + ay_1y_2)^2 - a(x_1y_2 + x_2y_1)^2.$$

Nonzero numbers of this form are closed under inversion using the trivial identity $1/t = t/t^2$:

$$\frac{1}{x^2 - ay^2} = \frac{x^2 - ay^2}{(x^2 - ay^2)^2} = \left(\frac{x}{x^2 - ay^2}\right)^2 - a\left(\frac{y}{x^2 - ay^2}\right)^2.$$ 

□

Definition 4.13. For $a \in F^\times$, let $N_a = N_a(F)$ be the set of all nonzero $x^2 - ay^2$ where $x, y \in F$. 
By Lemma 4.12 \(N_a\) is a subgroup of \(F^\times\), and \((F^\times)^2 \subset N_a\) using \(y = 0\).

**Theorem 4.14.** If \(a\) is a square in \(F\) then \(N_a = F^\times\).

**Proof.** Write \(a = c^2\) for \(c \in F^\times\). Then \(x^2 - ay^2 = x^2 - c^2y^2 = x^2 - (cy)^2 = (x - cy)(x + cy)\).

The change of variables \(x' = x - cy\) and \(y' = x + cy\) is invertible \(^2\) \((x = (x' + y')/2)\) and \(y = (y' - x')/(2c)\), so \(N_a = \{x'y' : x', y' \in F^\times\}\), which assumes all values in \(F^\times\) by choosing \(y' = 1\). \(\square\)

**Remark 4.15.** The converse of Theorem 4.14 is generally false: \(N_a\) could be \(F^\times\) without \(a\) being a square in \(F\). For instance, if \(F = \mathbf{F}_p\) for odd primes \(p\) then we’ll see in Corollary 4.24 that \(N_a = \mathbf{F}_p^\times\) for all \(a \in \mathbf{F}_p^\times\), but only half the elements of \(\mathbf{F}_p^\times\) are squares. There are important cases where the converse of Theorem 4.14 is true, such as \(F = \mathbf{Q}\) and \(F = \mathbf{R}\) (and \(F = \mathbf{Q}_p\) for any prime \(p\), if you know what \(\mathbf{Q}_p\) is).

We call \(N_a\) the **norm subgroup** of \(F^\times\) associated to \(a\), since \(x^2 - ay^2 = (x + y\sqrt{a})(x - y\sqrt{a})\) is usually called a norm.

**Theorem 4.16.** If \(b \in N_a\) then \((a, b)_F \cong M_2(F)\).

As a special case this includes \((a, b)_F \cong M_2(F)\) if \(b = \square \) in \(F\).

**Proof.** Write \(b = x_0^2 - ay_0^2\) with \(x_0\) and \(y_0\) in \(F\). The ring \((a, b)_F\) has a quaternionic basis (Definition 4.1):

\[
1, \ u, \ x_0v + y_0w, \ u(x_0v + y_0w).
\]

The fourth element is \(x_0v + y_0w\) by the formulas for \(uv\) and \(uw\). Why is this a basis? It is linearly independent since the 4th term is \(ay_0v + x_0w\) and the change of basis matrix from \(v, w\) to \(x_0v + y_0w, ay_0v + x_0w\) has determinant \(|_a y_0 w_0| = b \neq 0\) (Exercise 4.10). Therefore the above set of four elements of \((a, b)_F\) is linearly independent over \(F\), so it is a basis of \((a, b)_F\). Why is this basis quaternionic? We have \((x_0v + y_0w)^2 = bx_0^2 - aby_0^2 = b^2\), and \(u\) and \(x_0v + y_0w\) anti-commute. Therefore \(b \in N_a \Rightarrow (a, b)_F \cong (a, b^2)_F \cong (a, 1)_F \cong M_2(F)\). \(\square\)

**Example 4.17.** We have \((a, 1 - a)_F \cong M_2(F)\) if \(a \neq 0, 1\) since \(1 - a = x^2 - ay^2\) with \(x = y = 1\).

**Example 4.18.** The quaternion algebra \((3, 11)_\mathbf{Q}\) is a division ring since \(3 \neq \square \mod 11\), while \((3, -11)_\mathbf{Q} \cong M_2(\mathbf{Q})\) since \(-11 = x^2 - 3y^2\) with \(x = 1\) and \(y = 2\).

**Example 4.19.** When \(p\) is a prime and \(p = 2\) or \(p \equiv 1 \mod 4\), Fermat’s two-square theorem says \(p\) is a sum of two squares in \(\mathbf{Z}\). Therefore \(p \in N_{-1}(\mathbf{Q})\), so \((-1, p)_\mathbf{Q} \cong M_2(\mathbf{Q})\).

**Theorem 4.20.** A quaternion algebra \((a, b)_F\) that is not a division ring is isomorphic to \(M_2(F)\).

**Proof.** Since we already know that \((c^2, b)_F \cong M_2(F)\), we can assume \(a\) is not a square in \(F\).

By Theorem 3.8, if \((a, b)_F\) is not a division ring it contains a nonzero element \(q\) with \(N(q) = 0\). Let \(q = x_0 + x_1u + x_2v + x_3w\) with its coefficients not all equal to 0. Then

\[
N(q) = 0 \implies x_0^2 - ax_1^2 - bx_2^2 + abx_3^2 = 0 \implies x_0^2 - ax_1^2 = b(x_2^2 - ax_3^2).
\]

Since \(a\) is not a square in \(F\), we must have \(x_2^2 - ax_3^2 \neq 0\) by contradiction: if \(x_2^2 - ax_3^2 = 0\) then \(x_2 = 0\) (if \(x_3 \neq 0\) we could solve for \(a\) to see it is a square in \(F\)), so also \(x_2 = 0\), and that implies \(x_0^2 - ax_1^2 = 0\), so also \(x_1 = 0\) and \(x_0 = 0\), but then \(q = 0\).
Solving for $b$,
\[ b = \frac{x_2^2 - ax_3^2}{x_2^2 - ax_3^2} \in N_a, \]
so $(a,b)_F \cong M_2(F)$ by Theorem 4.16.

By this theorem, all $(a,b)_F$ that are not isomorphic to $M_2(F)$ are division rings, so

Non-split quaternion algebras $= \text{quaternion algebras that are division rings}$. 

**Theorem 4.21.** For $a$ and $b$ in $F^\times$, $(a,b)_F \cong M_2(F)$ if and only if $b \in N_a$.

**Proof.** If $b \in N_a$ then $(a,b)_F \cong M_2(F)$ by Theorem 4.16. Conversely, suppose $(a,b)_F \cong M_2(F)$. To show $b \in N_a$, we can assume $a$ is not a square in $F^\times$, since if $a$ were a square then $N_a = F^\times$ by Theorem 4.14, so obviously $b \in N_a$. When $(a,b)_F$ is not a division ring and $a$ is not a square, the proof of Theorem 4.20 shows $b \in N_a$. □

We have seen several sufficient conditions that imply $(a,b)_F \cong M_2(F)$:

- $b = c^2$: (4.1).
- $b = -a$: (4.1).
- $b = 1 - a$: Example 4.17.
- $b = x^2 - ay^2$ for some $x, y \in F$: Theorem 4.21.

The last condition includes the previous ones as special cases, and Theorem 4.21 tells us the last condition is not only sufficient but necessary as well.

**Remark 4.22.** We consider $M_2(F)$ to be the “trivial” quaternion algebra, so the following quaternion algebras $(a,b)_F$ are considered trivial: $(a,c^2)_F$, $(a,-a)_F$, $(a,1-a)_F$, and more generally $(a,x^2-ay^2)_F$. In other areas of math there are objects depending on two variables that turn out to be “trivial” in situations that resemble the conditions above. Probably the first instance of this historically was the Hilbert symbol $(a,b)_p$, where $p$ is a prime number and $a$ and $b$ are nonzero rational numbers (or even nonzero $p$-adic numbers). The Steinberg symbol $(a,b)_F$ for any field $F$ (of characteristic not 2) is a universal construction subject to rules typified by $(a,1-a)_F$ being considered “trivial.”

**Corollary 4.23.** For any $F$ not of characteristic 2, $H(F)$ is a division ring if and only if $-1$ is not a sum of two squares in $F$.

**Proof.** We will prove the negations of both conditions are equivalent: to say $H(F)$ is not a division ring means $H(F) \cong M_2(F)$, and by Theorem 4.21, $(-1,-1)_F \cong M_2(F)$ if and only if $-1 = x^2 - (y^2) = x^2 + y^2$ for some $x$ and $y$ in $F$. □

**Corollary 4.24.** For every odd prime $p$, all quaternion algebras over $F_p$ are isomorphic to $M_2(F_p)$.

This includes Example 4.7 as a special case.

**Proof.** We will show for all nonzero $a$ and $b$ in $F_p$ that $b = x^2 - ay^2$ for some $x$ and $y$ in $F_p$. Write the equation $b = x^2 - ay^2$ as $b + ay^2 = x^2$. Let’s count how many values each side of the equation has as $x$ and $y$ run over $F_p$. The total number of squares in $F_p$ is $(p+1)/2$ (not $(p-1)/2$, because we include 0 as a square), so $\#\{x^2\} = (p+1)/2$, and since $a \neq 0$ we also have $\#\{b+ay^2\} = (p+1)/2$. If the equation $b + ay^2 = x^2$ had no solution in $F_p$, then $\{x^2\}$ and $\{b+ay^2\}$ would be disjoint subsets of $F_p$, but their sizes add up to $(p+1)/2 + (p+1)/2 = p+1 > |F_p|$, so we’d have a contradiction. Therefore there exist some $x$ and $y$ in $F_p$ such that $b + ay^2 = x^2$. □
In Theorem 4.21, the condition \((a, b)_F \cong M_2(F)\) is symmetric in \(a\) and \(b\) since \((a, b)_F \cong (b, a)_F\). Therefore the condition \(b \in N_a\) has to be symmetric in \(a\) and \(b\) even though it doesn’t look symmetric in \(a\) and \(b\) at first glance. (That is, being able to solve \(b = x^2 - ay^2\) in \(F\) may not look obviously equivalent to being able to solve \(a = x^2 - by^2\) in \(F\), particularly if one of the squares in a solution is 0.) The following alternate form of Theorem 4.21 replaces “\(b \in N_a\)” with conditions on an equation involving \(a\) and \(b\) that are visibly symmetric.

**Theorem 4.25.** For \(a\) and \(b\) in \(F^\times\), the following conditions are equivalent:

1. \((a, b)_F \cong M_2(F)\),
2. the equation \(ax^2 + by^2 = 1\) has a solution \((x, y)\) in \(F\),
3. the equation \(ax^2 + by^2 = z^2\) has a solution \((x, y, z)\) in \(F\) other than \((0, 0, 0)\).

**Proof.** Exercise 4.12.

**Corollary 4.26.** For \(a\) and \(b\) in \(F^\times\), the following conditions are equivalent:

1. \((a, b)_F\) is a division ring,
2. the equation \(ax^2 + by^2 = 1\) has no solution \((x, y)\) in \(F\),
3. the only solution to \(ax^2 + by^2 = z^2\) in \(F\) is \((0, 0, 0)\).

**Proof.** Negate each part of Theorem 4.25.

Exercises.

1. Show (4.2) is multiplicative.
2. If \(e_1, e_2 \in (a, b)_F\) satisfy the conditions \(e_1^2 \in F^\times, e_2^2 \in F^\times, e_1e_2 = -e_2e_1,\) and \(e_1^2\) and \(e_2^2\) are not in \(F^\times^2\), show \([1, e_1, e_2, e_1e_2]\) is a linearly independent set. Remember, \(F\) has characteristic \(\neq 2\). (Hint: If \(x_0 + x_1e_1 + x_2e_2 + x_3e_1e_2 = 0\) where \(x_i \in F\), write this as \((x_0 + x_1e_1) + (x_2 + x_3e_1)e_2 = 0\) and multiply on the left by \(x_2 - x_3e_1\). Note \(x_2^2 - x_3^2e_1^2 \neq 0\) unless \(x_2 = x_3 = 0\), since \(e_1^2 \notin F^\times^2\).)
3. Under the isomorphism \((a, 1)_F \cong M_2(F)\) determined by

\[
1 \mapsto \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad u \mapsto \begin{pmatrix} 0 & 1 \\ a & 0 \end{pmatrix}, \quad v \mapsto \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad w \mapsto \begin{pmatrix} 0 & -1 \\ a & 0 \end{pmatrix}
\]

what element of \((a, 1)_F\) corresponds to the matrix \(\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}\)?
4. Under the isomorphism \((1, 1)_F \cong M_2(F)\) as in the previous exercise (with \(a = 1\)), let \(x_0 + x_1u + x_2v + x_3w\) in \((1, 1)_F\) correspond to \((\alpha, \gamma)\) in \(M_2(F)\). Write \(\alpha, \beta, \gamma, \delta\) in terms of \(x_0, x_1, x_2, x_3\) and vice versa. Check that, under this isomorphism, the norm on \((1, 1)_F\) corresponds to the determinant on \(M_2(F)\), but conjugation on \((1, 1)_F\) does not correspond to the transpose on \(M_2(F)\). What operation on \(M_2(F)\) corresponds to conjugation on \((1, 1)_F\)?
5. When \(a \neq -b\) in \(F^\times\), check \([1, u + v, w, (u + v)w]\) is a quaternionic basis of \((a, b)_F\). Therefore \((a, b)_F \cong (a + b, -ab)_F\). For example, \((2, 3)_Q \cong (5, -6)_Q\).
6. Show \(-1\) is not a sum of two squares in the field \(Q(\sqrt{-7})\), so \(H(Q(\sqrt{-7}))\) is a division ring. Is \(H(Q(\sqrt{-2}))\) a division ring?
7. If \(a, b \in F^\times\) satisfy \(a + b = c^2\) for some \(c \in F\), show \((a, b) \cong M_2(F)\).
8. By Theorem 4.16,

\[
b = x_0^2 - ay_0^2\]

for some \(x_0, y_0 \in F \implies (a, b)_F \cong M_2(F)\)
by using the quaternionic basis \( \{1, u, x_0v + y_0w, u(x_0v + y_0w)\} \) of \((a, b)_F\). What is wrong with the following alternate proof of the above implication?

If \(x_0 = 0\), then \(y_0 \neq 0\) and \((a, b)_F = (a, -ay^2_0)_F \cong (a, -a)_F \cong M_2(F)\).

If \(x_0 \neq 0\), then \((yu + v)^2 = x_0^2\) and the set \(\{1, u, y_0u + v, u(y_0u + v)\}\) is a basis of \((a, b)_F\), so \((a, b)_F \cong (a, x_0^2)_F \cong M_2(F)\).

9. A quaternion algebra over \(F\) is isomorphic to \(M_2(F)\) precisely when it has a nonzero element with norm 0. Prove \((a, -a)_F \cong M_2(F)\) if \(a \neq 0\), and \((a, 1 - a)_F \cong M_2(F)\) if \(a \neq 0, 1\) by finding specific nonzero elements in them with norm 0.

10. In \(F^n\), let \(v_1\) and \(v_2\) be linearly independent. For \(a, b, c, d \in F\), show \(av_1 + bv_2\) and \(cv_1 + dv_2\) are linearly independent in \(F^n\) if and only if the determinant \(\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc\) is nonzero.

11. Decide if the following are division rings: \((2, -5)_Q, (6, 10)_Q, (6, -10)_Q, (5, 11)_Q, (5, -11)_Q\).

5. ISOMORPHISM AND NORMS

Theorem 4.21 can be expressed as: \((a, b)_F \cong (a, 1)_F\) if and only if \(b \in N_a\). The following theorem generalizes this.

**Theorem 5.1.** For \(a, b, b' \in F^\times\), \((a, b)_F \cong (a, b')_F\) if and only if \(b/b' \in N_a\).

**Proof.** The direction (\(\Leftarrow\)) is much simpler, so we do that first. Suppose \(b/b' = x_0^2 - ay_0^2\) for some \(x_0\) and \(y_0\) in \(F\). Let \(\{1, u, v, uv\}\) be the usual quaternionic basis of \((a, b')_F\). Check that

\[(5.1) \quad 1, \ u, \ x_0v + y_0w, \ u(x_0v + y_0w),\]

is also a quaternionic basis of \((a, b')_F\). Here \(u^2 = a\) and \((x_0v + y_0w)^2 = b'x_0^2 - ab'y_0^2 = b'(b/b') = b\), so \((a, b')_F \cong (a, b)_F\).

To prove the reverse direction, that \((a, b)_F \cong (a, b')_F \Rightarrow b/b' \in N_a\), the isomorphic quaternion algebras \((a, b)_F\) and \((a, b')_F\) are either both division rings or both not division rings.

First suppose \((a, b)_F\) and \((a, b')_F\) are not division rings, so they are isomorphic to \(M_2(F)\). Then \(b \in N_a\) and \(b' \in N_a\) by Theorem 4.21. Since \(N_a\) is a subgroup of \(F^\times\), \(b/b' \in N_a\).

Next suppose \((a, b)_F\) and \((a, b')_F\) are division rings, so in particular \(a\) is not a square in \(F\). Let \(\{1, u, v, uv\}\) be the standard quaternionic basis of \((a, b')_F\), so

\[u^2 = a, \ v^2 = b', \ uv = -vu.\]

Since \((a, b')_F \cong (a, b)_F\), \((a, b')_F\) contains a quaternionic basis \(\{1, u_0, v_0, u_0v_0\}\) where

\[u_0^2 = a, \ v_0^2 = b, \ u_0v_0 = -v_0u_0.\]

The polynomial \(T^2 - a\) is irreducible over \(F\) since \(a\) is not a square in \(F\), and both \(u\) and \(u_0\) are roots of this polynomial in \((a, b')_F\), so Theorem B.2 implies \(u = qu_0q^{-1}\) for some nonzero \(q \in (a, b')_F\). Set \(v = qv_0q^{-1}\), so \(v^2 = (qv_0q^{-1})(qv_0q^{-1}) = qv_0q^{-1} = qbq^{-1} = b\). Then

\[u_0v_0 = -v_0u_0 \Rightarrow (qu_0q^{-1})(qv_0q^{-1}) = -(qv_0q^{-1})(qu_0q^{-1}) \Rightarrow uv = -vu.\]
The elements of \((a, b')_F\) that anti-commute with \(u\) are \(Fv + Fw\) (Exercise 3.3), so \(\bar{v} = xv + yw\) for some \(x\) and \(y\) in \(F\). Then
\[
b = \bar{v}^2 = (xv + yw)^2 = b'x^2 - b'ay^2 = b'(x^2 - ay^2) \implies \frac{b}{b'} \in \mathbb{N}_a.
\]

\[\square\]

**Remark 5.2.** Theorem 5.1 gives us a new proof that \((a, -ab)_F \cong (a, b)_F\): \(-a = x^2 - ay^2\) with \(x = 0\) and \(y = 1\). It might appear that this theorem reproves \((a, bc^2)_F \cong (a, b)_F\) \((c^2 = x^2 - ay^2\) with \(x = c\) and \(y = 0\)), but this is circular because we will be using that isomorphism in the proof of Theorem 5.1.

**Example 5.3.** \((2, 3)_Q \cong (2, 21)_Q\) since \(21/3 = 7 = x^2 - 2y^2\) using \(x = 3\) and \(y = 1\).

**Example 5.4.** To decide if the division rings \((2, 3)_Q\) and \((2, 5)_Q\) are isomorphic is equivalent to deciding if \(5/3 = x^2 - 2y^2\) for some rational numbers \(x\) and \(y\). This equation has no rational solution (Exercise 5.3a), so \((2, 3)_Q \not\cong (2, 5)_Q\).

**Corollary 5.5.** For distinct primes \(p\) and \(q\) that are \(3\) mod \(4\), \((-1, p)_Q\) is not isomorphic to \((-1, q)_Q\).

**Proof.** If \((-1, p)_Q \cong (-1, q)_Q\) then \(q/p \in \mathbb{N}_{-1}(Q)\), so \(q/p = x^2 + y^2\) for some rational numbers \(x\) and \(y\). Write \(x\) and \(y\) with a common denominator: \(x = m/d\) and \(y = n/d\) with integers \(m, n,\) and \(d\) where \(d \neq 0\). Then
\[
qd^2 = p(m^2 + n^2).
\]

Since \(p \neq q\), \(m^2 + n^2 \equiv 0 \mod q\). That implies \(m\) and \(n\) are divisible by \(q\) (because \(-1 \mod q\) is not a square), so \(qd^2\) is divisible by \(q^2\), and thus \(q/d\) in the equation \(qd^2 = p(m^2 + n^2)\) the numbers \(m, n,\) and \(d\) are all divisible by \(q\), so we can divide through by \(q^2\) and get a similar equation where \(m, n,\) and \(d\) are replaced by \(m/q, n/q,\) and \(d/q\). Repeating this \(\text{ad infinitum}d\) is divisible by arbitrarily high powers of \(q\), a contradiction. \[\square\]

There are infinitely many primes congruent to \(3\) mod \(4\), so Corollary 5.5 shows there are infinitely many non-isomorphic quaternion algebras over \(Q\)!

**Theorem 5.6.** If \(f: A_1 \to A_2\) is an isomorphism of quaternion algebras over \(F\) then we have \(f(q) = f(\bar{q})\) for all \(q \in A_1\). In particular, \(N(f(q)) = N(q)\).

**Proof.** Once we show \(f(q) = f(\bar{q})\) for all \(q \in A_1\) we get
\[
N(f(q)) = f(q)f(\bar{q}) = f(q)f(\bar{q}) = f(q\bar{q}) = f(N(q)) = N(q)
\]
since \(N(q) \in F\) and \(f\) fixes all elements of \(F\).

Write \(q = x_0 + q_0\) where \(x_0 \in F\) and \(q_0\) is a pure quaternion in \(A_1\) (Example 3.7). Then
\[
f(q) = f(x_0 + q_0) = x_0 - f(q_0).
\]

We will show \(f(q_0)\) is a pure quaternion in \(A_2\). This is obvious if \(q_0 = 0\), so assume \(q_0 \neq 0\). Since \(q_0\) is pure in \(A_1\) we have \(q_0^2 \in F\) by (3.2), so also \(f(q_0)^2 \in F\). By Exercise 3.6 ii, either \(f(q_0)\) is pure or \(f(q_0) \in F\). We can’t have \(f(q_0) \in F\) since \(f(F) = F\), \(f\) is injective, and \(q_0 \notin F\) (the only pure quaternion in \(F\) is \(0\)). Thus \(f(q_0)\) is pure, so \(f(q_0) = -f(q_0)\), which turns (5.2) into
\[
f(\bar{q}) = x_0 + f(q_0) = x_0 + f(q_0) = f(x_0 + q_0) = f(q).
\]

\[\square\]
Corollary 5.7. If $A_1$ and $A_2$ are isomorphic quaternion algebras over $F$ then the norm maps $A_1 \rightarrow F$ and $A_2 \rightarrow F$ have the same image.

Proof. This is immediate from $N(q) = N(f(q))$ for any isomorphism $f : A_1 \rightarrow A_2$. \qed

Example 5.8. The quaternion algebras $H(Q)$ and $(2,3)_Q$ are division rings (for $(2,3)_Q$ see Example 3.10), but they are not isomorphic quaternion algebras over $Q$ since the norm on $H(Q)$ is nonnegative and the norm on $(2,3)_Q$ has negative values by Example 3.6.

Exercises.

1. In the proof of Theorem 5.1, show (5.1) is a quaternionic basis of $(a,b)_F$.
2. Let $a,b,b' \in F^\times$.
   a) If $(a,b)_F \cong M_2(F)$, prove $(a,b')_F \cong (a,bb')_F$. (For example, if $p = 2$ or $p \equiv 1 \bmod 4$, then we already know $(p,-1)_Q \cong M_2(Q)$, so $(p,r)_Q \cong (p,-r)_Q$ for any $r \in Q^\times$.) Is the converse true?
   b) By part a, $(2,3)_Q \cong (2,-3)_Q$. Show $(-2,3)_Q \cong M_2(Q)$ and $(-2,-3)_Q \cong H(Q)$.
3. If $p$ is a prime number such that $p \equiv 3$ or $5 \bmod 8$, then $(p,2)_Q$ is a division ring by Exercise 3.5.
   a) Show the equation $5/3 = x^2 - 2y^2$ has no rational solution, so $(3,2)_Q \not\cong (5,2)_Q$. (Hint: Mimic the proof of Corollary 5.5.)
   b) For distinct primes $p$ and $q$ that are 3 or 5 mod 8 (this means $p \equiv 3$ or 5 mod 8 and $q \equiv 3$ or 5 mod 8), show $(p,2)_Q$ is not isomorphic to $(q,2)_Q$.
   c) Prove the converse of Exercise 3.5 is false by showing $(15,2)_Q$ and $(33,2)_Q$ are division rings. Neither 15 nor 33 is 3 or 5 mod 8.

Appendix A. Sum of square identities using $C$ and $H$

In $C$, the fact that $zw = \overline{zw}$ implies a formula for the product of sums of two squares as a sum of two squares:

(A.1) 
\[
(a^2 + b^2)(c^2 + d^2) = (ac - bd)^2 + (ad + bc)^2.
\]

Writing $z = a + bi$ and $w = c + di$, the left side is $z\overline{zw}$ and the right side is $z\overline{w}w = z\overline{zw}$.

Quaternionic multiplication in $H$ leads to a four-square identity generalizing (A.1):

\[
(a_1^2 + b_1^2 + c_1^2 + d_1^2)(a_2^2 + b_2^2 + c_2^2 + d_2^2) = (a_1a_2 - b_1b_2 - c_1c_2 - d_1d_2)^2 + (a_1b_2 + b_1a_2 + c_1d_2 - d_1c_2)^2 + (a_1c_2 - b_1d_2 + c_1a_2 + d_1b_2)^2 + (a_1d_2 + b_1c_2 - c_1b_2 + d_1a_2)^2.
\]

To prove this, any sum of four squares is the norm of a quaternion: $a^2 + b^2 + c^2 + d^2 = N(a + bi + cj + dk)$. Letting $q_1 = a_1 + b_1i + c_1j + d_1k$ and $q_2 = a_2 + b_2i + c_2j + d_2k$ in $H$, feeding these into the formula $N(q_1)N(q_2) = N(q_1q_2)$ from (2.3) implies the four-square identity above.

It’s hard to imagine the four-square identity could be found without quaternions, but it was! Unbeknownst to Hamilton, the four-square identity was written down by Euler in 1748, a hundred years before the discovery of quaternions.
Appendix B. Conjugates in a division ring

The label “conjugates” in the heading of this appendix doesn’t refer to the conjugation operation on a quaternion algebra, but rather to conjugation in the sense of group theory: elements \( x \) and \( y \) in a group \( G \) are called conjugate when \( y = gxg^{-1} \) for some \( g \in G \). For a division ring \( D \), its nonzero elements are a group under multiplication and we call \( x \) and \( y \) in \( D \) conjugate if \( y = dxd^{-1} \) for some \( d \in D^\times = D - \{0\} \).

When \( F \) is a field, a polynomial of degree \( n \) in \( F[t] \) has at most \( n \) roots in \( F \). Surprisingly, over a division ring a polynomial of degree \( n \) can have more than \( n \) roots. For example, the polynomial \( t^2 + 1 \) has infinitely many roots in \( \mathbb{H} \): by (2.1), any pure quaternion \( bi + cj + dk \) with \( b^2 + c^2 + d^2 = 1 \) is a root of \( t^2 + 1 \). As if to compensate for there being more roots than the degree, all these roots turn out to be conjugate to each other in the sense of group theory: if \( x^2 + 1 = 0 \) and \( y^2 + 1 = 0 \) in \( \mathbb{H} \) then \( y = qxq^{-1} \) for some \( q \in \mathbb{H}^\times \). This is a special case of the following general theorem of Dickson. Recall (Exercise 2.3) that the center of a division ring is a field.

Theorem B.1 (Dickson). Let \( D \) be a division ring with center \( F \) and \( f(t) \) be an irreducible polynomial in \( F[t] \). Any two roots of \( f(t) \) in \( D \) are conjugate to each other: if \( f(x) = 0 \) and \( f(y) = 0 \) for \( x \) and \( y \) in \( D \) then \( y = dxd^{-1} \) for some \( d \in D^\times \).

A proof of Theorem B.1 can be found in [4, Theorem 16.8]. We use this result (in Section 5) only when \( \dim_F(D) < \infty \) and \( \deg f = 2 \), so we’ll prove Theorem B.1 in this special case:

Theorem B.2. Let \( D \) be a division ring with center equal to a field \( F \), and assume \( \dim_F(D) < \infty \). If \( f(t) = t^2 + c_1 t + c_0 \in F[t] \) is irreducible over \( F \) then any \( x \) and \( y \) in \( D \) satisfying \( f(x) = 0 \) and \( f(y) = 0 \) are conjugate: \( y = dxd^{-1} \) for some \( d \in D^\times \).

Proof. We have \( x^2 + c_1 x + c_0 = 0 \) and \( y^2 + c_1 y + c_0 = 0 \). Therefore \( y^2 + c_1 y = x^2 + c_1 x \), and by adding \( xy \) to both sides we can write this equation in the clever way

\[
y(y + x + c_1) = (y + x + c_1)x
\]

If \( y + x + c_1 \neq 0 \) then set \( d = y + x + c_1 \), so \( yd = dx \) and \( d \neq 0 \) in \( D \). Thus \( y = dxd^{-1} \).

What if \( y + x + c_1 = 0 \)? In that case, to find a nonzero \( d \) that makes \( yd = dx \) requires a bit of linear algebra. Define \( L: D \to D \) by \( L(d) = dx - yd \) for all \( d \in D \). Since \( F \) is the center, \( L \) is \( F \)-linear:

\[
L(d_1 + d_2) = (d_1 + d_2)x - y(d_1 + d_2) = d_1x - yd_1 + d_2x - yd_2 = L(d_1) + L(d_2),
\]

\[
L(cd) = (cd)x - y(cd) = cdx - cyd = c(dx - yd) = cL(d),
\]

where \( c \in F \). Since \( y + x + c_1 = 0 \), \( L(d) = dx + (x + c_1)d \). This formula implies \( xL(d) = yL(d) \):

\[
xL(d) = x(dx + (x + c_1)d) = xdx + (x^2 + c_1x)d = xdx - c_0d,
\]

\[
L(d)x = dx^2 + (x + c_1)dx = d(-c_1x - c_0) + xdx + c_1dx = xdx - c_0d,
\]

and these two values are equal. Thus \( L(d) \) commutes with \( x \) for all \( d \in D \).

Since \( f(x) = 0 \) and \( f(t) \) has no roots in \( F \), \( x \notin F \). All of \( L(D) \) commutes with \( x \), and not all of \( D \) commutes with \( x \) (otherwise \( x \) would be in the center of \( D \), which is \( F \)), so \( L(D) \) is a proper subspace of \( D \): \( L \) is not surjective. A basic theorem from linear algebra says a linear map \( V \to V \) where \( \dim_F(V) < \infty \) is one-to-one if and only if it is onto. Since \( L \) is not onto and \( \dim_F(D) < \infty \), \( L \) is not one-to-one: \( \ker L \neq \{0\} \). Therefore some nonzero \( d \in D \) satisfies \( L(d) = 0 \), which means \( dx = yd \). Thus \( y = dxd^{-1} \). \( \square \)
References
